FOREWORD

I remember being slightly surprised when I first heard that a second edition of the *Encyclopedia of Language and Linguistics* (ELL2) was in the works: I wondered if it wasn't premature, a bit too soon after the first edition. But now that I see the result, it is clear that this new edition is both timely and a major advance over the very successful ELL1. Linguistics is a fast-moving field.

Theoretical controversies continue and develop; linguistic and sociolinguistic data collection has increased rapidly over the past 10 years or so, stimulated in large part by linguists' awareness of the critical problem of language endangerment; the greatly expanded role of digital resources is making huge bodies of data available to all scholars; and interdisciplinary outreach by linguists and to linguistics has made our discipline a bit more visible beyond the in-group. We and our students still hear the same old question all too often – "What is linguistics, anyway?" – but within academia, at least, colleagues in other disciplines now tend to be embarrassed to ask it, even if they don't know the answer.

All these developments make this encyclopedia an invaluable reference work. By 1990 it was already impossible (as I know all too well from my years as editor of a general linguistics journal) for any linguist to have expert knowledge of the entire range of the discipline, much less of the interdisciplinary areas that were beginning to take on new prominence. The past 15 years have seen remarkable developments, so that it is now difficult to imagine being familiar with more than a smallish fraction of the many advances in our understanding of language and linguistics. Having access to a quick survey of current issues and sources on language and the brain, morphological theory, statistical methods in language processing, categorial grammars, the classification of Austronesian languages, dialects in bird songs, second-language attrition, bilingual education, the CHILDES database, and hundreds of other topics will delight and inform linguists and, I predict, a great many non-linguists as well. The numerous articles on interdisciplinary topics should be especially valuable for linguists with limited knowledge of the other disciplines as well as for non-linguists with an interest in interface issues.

Another feature of ELL2 struck me as I began to prepare to teach a new course on social, political, and economic implications of multilingualism: this encyclopedia will be an excellent resource for my students, because it has a whole range of articles on relevant topics, including a set on the language situation in countries all over the world and another set on language education policies in the world's major regions. Other course instructors will surely also be happy to send their students to this work, for courses on language and the brain, animal communication, second-language acquisition, and any number of other general topics.

From people who enjoy browsing through encyclopedias to specialists who want some basic orientation in an area near their own, readers will find ELL2 to be an outstanding source of information.

Sarah G. Thomason
William J. Gedney Collegiate Professor of Linguistics
University of Michigan, Ann Arbor, USA

INTRODUCTION

The first edition of the *Encyclopedia of Language and Linguistics* (ELL1), with R. E. Asher as Editor-in-Chief and J. M. Y. Simpson as Coordinating Editor, was published in 1994. It was intended to be 'authoritative, comprehensive, international and up-to-date.' The reviews show that it largely succeeded in these aims.

When in 2002 I was invited by Chris Pringle (Publisher, Elsevier Social Sciences), to be Editor-in-Chief of a new edition of ELL, I assumed that what Elsevier had in mind was a revision of ELL1. However it soon became clear in discussions with Chris and with Sarah Oates (Linguistics Publishing Editor) that this was not at all what was intended. In the 10 years since the first edition was published, linguistics had grown explosively, both in its own specializations and in interdisciplinary fields. We decided that ELL2 should reflect this growth and be an entirely new work, with new and expanded sections, new topics, new editors, new authors, and newly commissioned articles. At the same time, we wanted to retain the broad vision of ELL1 as an encyclopedia concerned both with languages and with linguistics. We have therefore sought to deal comprehensively with the current state of the fundamental linguistic disciplines, with their applications to the study of language, and with the interdisciplinary relationships between linguistics and the other disciplines from which it draws inspiration and to which it contributes expertise. We have also sought to retain, and indeed expand on, ELL1's coverage of the languages of the world.

We also planned to publish the Encyclopedia in two versions, a 14-volume print version and, in parallel, an online version available at http://www.sciencedirect.com. The two versions have the same text, but the online version supplements the written text with additional illustrative material that is only possible in an electronic version – samples of spoken or signed language, videos of the use of language in context, and the like.

Our first task was to set up an Editorial Board. This consisted of the Editor-in-Chief and six Coordinating Editors, each having general oversight over a particular area of the encyclopedia. We were fortunate in being able to recruit as Coordinating Editors Jim Miller and Laurie Bauer (who between them covered the fundamental linguistic disciplines of phonetics, phonology, morphology, syntax, semantics, pragmatics, and discourse), Anne Anderson (psychololinguistics and cognitive science), Graeme Hirst (computational applications of linguistics), and Margie Berns (applied linguistics and applications of linguistics in education, the law, politics, the media, and so on). We had hoped that Seumas Simpson, who had been Coordinating Editor for ELL1, would be able to join us as Coordinating Editor for languages, writing systems, biographies, and the history of the subject, but unfortunately that turned out not to be possible, so I took on the task of the sixth Coordinating Editor. The first meeting of this editorial board and Elsevier was at Woodstock in 2002. By good fortune, both Ron Asher and Seumas Simpson also attended this meeting, so we were able to draw on their experience of ELL1. At this meeting we determined the overall architecture of ELL2, drew up the list of sections, set the general scope of each, and began to think about Section Editors.

The six Coordinating Editors were invited to find an editor for each of the sections in their general area, and these Section Editors, as they were recruited, were invited to take primary responsibility for a particular subject area. They were also invited to join an Executive Editorial Board. ELL1 had 34 editors, ELL2 has 45; full details of the board are included in the front matter. The names of many of the ELL1 sections have been retained – pragmatics, semantics, syntax, morphology, phonetics, phonology, and so on – but in all cases the structure of the sections and their contents have been rethought and articles freshly commissioned. Some ELL1 sections in

which there have been substantial recent developments or that we felt were rather scantily covered in ELL1 have been considerably expanded, and new sections have been added. In the area of syntax and morphology there is a new section on typology and universals; in the area of psycholinguistics there are new sections on language acquisition and on cognitive science, and the ELL1 section on language pathology has been expanded into a section on brain and language dealing not only with language disorders but also with the contemporary developments in neurolinguistics. In the area of text linguistics and discourse there are now separate sections on written and spoken discourse and a set of new sections on discourse in particular fields – medicine, the law, the media, politics, etc. The section on computational linguistics and natural language processing has been expanded in line with recent developments, and there is a new section on speech technology. New developments in pragmatics have likewise been taken into account: intercultural pragmatics, pragmatics of reading, pragmatic acts, and others. There is increased coverage of biographies and of languages.

In 2003 we held a meeting of all the editors. For this meeting, each of the Section Editors was asked to articulate the coverage of their section, to draw up lists of article titles, and to begin to think of authors. As a group we scrutinized the Section Editors' proposals, examined their lists of articles, proposed further titles, and attempted to identify gaps in coverage and to plug them. This process of determining the coverage of the encyclopedia did not, of course, end with this meeting, but was continually negotiated over several more months. Finally, we also proposed a small international Honorary Editorial Advisory Board to scrutinize our plans and comment on them: Barry Blake (La Trobe), Yukio Otsu (Keio), Sally Thomason (Michigan), Yueguo Gu (Beijing), and Nigel Vincent (Manchester). We are grateful for their help and advice. The extent to which the encyclopedia meets its aims of being comprehensive and authoritative is due to the expertise and dedication of the members of the editorial boards, the Coordinating Editors and Subject Editors, the international advisors, and of course the authors. We are particularly pleased that the authorship is truly international. Our authors come from more than 70 different countries: some 45% are from Europe and some 40% from North America. A full list can be found in the list of contributors.

The large number of editors and sections gave rise to a general structural problem. Some division of editorial responsibility was necessary in order to cover a subject so wide-ranging and interdisciplinary as linguistics. It will be clear from the list of section editors and their commissioning responsibilities, and from the subject classification, that our sections correspond largely to the traditional partitioning of linguistics into syntax, semantics, pragmatics, etc., and also recognizes the customary applications in psycholinguistics, sociolinguistics, comparative linguistics, computational linguistics, and so forth. In many of the proposed sections, even within the more centrally linguistic disciplines, the phenomena that we are dealing with are not readily classifiable as belonging exclusively to one area. Consequently, there is on the one hand the possibility of overlap, and on the other, the possibility of gaps in coverage. Overlap, where it does not involve repetition, is not necessarily vicious because it can offer revealingly different perspectives on particular issues, and in a project as large as this, it is difficult to avoid. We have tried our best to minimize any gaps. All the editors were involved in scrutinizing the list of articles to try and identify and fill gaps, and it was a general editorial policy that there was no strict demarcation between the responsibilities of the various editors, who were encouraged to negotiate their area of responsibility with other neighboring areas to ensure that the coverage was as complete as possible.

In a fast-changing and developing field like linguistics it is important for a work called an encyclopedia both to be up-to-date and to remain in contact with its traditions. In the central areas of linguistics it is probably the case that many of the fundamentals have remained much as they were 10 years ago, but they should be reinterpreted in the light of new data or new theoretical positions. They need to be restated for a new generation to inform the student and offer suitable background information to the researcher or professional from a related area who seeks to understand linguistics.

The various subdisciplines have developed rapidly. Linguistics, like other disciplines in the arts and social sciences, is driven by both theory and data and the interaction between the two. So in the 10 years since ELL1 we have seen the arrival of new theories and the fading of old ones in the fundamental linguistic disciplines as well as in interdisciplinary areas. It is interesting to see how work in the linguistic disciplines increasingly draws insights from interdisciplinary cooperation, and it is striking how different the bibliographies in ELL2 are from those in ELL1.

In the same period, we have also seen a considerable increase in the amount of data available. There is more data on individual languages, which is reflected in the language articles, and substantially more on basic linguistic phenomena of both typological and universal issues: on topics such as the word, complementation, case, tense, aspect, and modality, and on functional domains such as possession and comparison. Data feeds

theory, and these phenomena are as likely to be covered in the interdisciplinary sections as they are, for example, in the sections on morphology or syntax.

Another area of substantial change since ELL1 is the development of new technologies. Developments in computer technology have made it possible to assemble substantial corpora of spoken and written text, and analysis tools have improved beyond measure so that in many areas corpus linguistics has had a substantial impact on both description and theory. The Internet, text-messaging on mobile phones, online chat groups, and the like bring new dimensions to the use of language in the media and to the study of discourse in general. Similarly, new technologies for investigating speech and neural activity open up new insights on the mental storage and processing of language.

All these developments have led to a considerable increase in the amount of interdisciplinary work in linguistics. For example, developments in psycholinguistic theory have been influential in many areas – so much so that linguistic investigations are now likely to be conducted in departments other than Departments of Linguistics – as can be seen by looking at the departmental affiliations of the Section Editors and authors. This renders the distinction between the 'core' and the 'periphery' of linguistics, which was still being drawn in ELL1, no longer as viable as it once may have seemed.

ELL2 has attempted to address some of these issues by systematically including articles on interfaces between disciplines and, in the subject classification, by listing individual articles under more than one classification. This also implies that the classification does not entirely correspond to the commission responsibilities of individual Section Editors.

We have tried to be comprehensive in our coverage. The articles are ordered alphabetically by title, so the reader who wishes to see the coverage in a particular area will find it helpful to consult the subject classification. What follows is a brief explication of the classification and the coverage of each section.

Foundations of linguistics explores fundamental linguistic concepts as they relate to linguistic theories and to the collection and organization of data. Many of these foundational issues are also discussed, from a philosophical point of view, in the section on philosophy and language and from other perspectives in other sections. The section also broaches issues relating to the origin and evolution of language.

The section on **animal communication** discusses the complex communicative signals that non-human individuals across the animal kingdom have evolved to communicate information about themselves, their age, their individual identity, their social status, etc., and also their capacity for referential signaling about external objects such as the location of food sources or specific information about predators. Animal communication is a greatly expanding field of research by biologists and psychologists that can make a significant contribution to understanding human language. In the online version there are multimedia annexes that give a wide range of examples of animal communication, from the bee dance to fish communication.

The section on issues in **semiotics** deals with theories of the sign as they apply both to linguistics and to other communicative activities and other modalities such as music.

It is to be expected that an encyclopedia of linguistics should pay major attention to the fundamental disciplines at the heart of all linguistic investigations: phonetics, phonology, morphology, syntax, semantics, pragmatics, and discourse. In each of these areas there are articles on fundamental concepts of the discipline, on models within the discipline, and on interfaces with other linguistic disciplines as well as on interdisciplinary links.

Phonetics is the study of the way speech sounds are produced and interpreted. This includes the articulation and perception of speech sounds and investigations into the character of and the explanation for the universal constraints on the structure of speech sound inventories and speech sound sequences. It increasingly encompasses the design of mechanical systems to code, transmit, synthesize, and recognize speech. It also includes the study of how speech sounds vary in different styles of speaking, in different phonetic contexts, over time, and over geographical regions; how children first learn the sounds of their mother tongue; how best to learn to pronounce the sounds of another language; and investigations into the causes of and the therapy for defects of speech and hearing. These issues are relevant to more than one section. In the online version many of the articles are accompanied by audio files.

The boundary between phonetics and **phonology,** the study of the more abstract, more functional, and more psychological aspects of speech, is under constant debate. Phonology is the study of sound systems in language and was the first subdiscipline in which the view of language as a system was developed successfully. The section discusses the nature of phonological units and processes, both at the segmental and at the prosodic level and illustrates this with descriptions of the phonological systems of a number of typologically different languages.

Morphology is concerned with the relationship between the form of a word and its meaning. Since morphology is interested in the forms of words, it is related to phonology for the study of the sound shapes of words and to syntax both for the study of the composition of words and for their syntactic function. And because morphology is concerned with meaning, it is related to the study of semantics and of the lexicon. These many relationships mean that morphological theorizing has been much influenced by phonological and syntactic theories, as well by changing ideas about the nature of the lexicon. Morphological processes, inflection, derivation, and so on remain at the heart of morphology and are fully covered in the encyclopedia, as are more recent developments in morphological typology and the study of morphology within psycholinguistics.

Linguistics has always been concerned with developing a general theory of the structure and nature of language while making its theorizing as empirically viable and as explanatory as possible. Nowhere has this aim been more rigorously pursued than in the field of syntax. **Syntax** is concerned with modeling the combination of words and morphemes to build more complex meanings. The encyclopedia takes no party line with respect to syntactic theory, and there are articles covering the main ideas of various syntactic theories, thus, for example, ideas underlying generative grammar are explored in the article 'History of Linguistics: Discipline of Linguistics,' those underlying relational grammar in the article 'Grammatical Relations and Arc-Pair Grammar,' and the principles underlying cognitive grammar are explored in a number of articles. The syntax section of the subject classification contains an overview of the syntactic theories explored in the encyclopedia: it includes articles on theories that were prominent a decade ago but are falling out of the spotlight, on those that remain the subject of vigorous development, and on those that have come to prominence over the last decade.

These sections inevitably raise questions about linguistic and typological universals. The section on **typology and universals** concentrates on these issues and is concerned mainly, but not exclusively, with research findings made in the course of the last decade, deriving either from functionally oriented research or from generative paradigms. There are articles reflecting recent findings on the typology of linguistic categories in, for example, grammatical domains such as evidentiality, reference marking, and serial verb construction. This section also covers 'areal' linguistics, a field of increasing interest; since areal linguistics has a historical dimension, these articles intersect with the section on historical and comparative linguistics.

I remarked earlier that phonology was the first subdiscipline in which the contemporary view of language as a system was developed successfully. In the middle of the 20th century the spotlight turned from phonology and morphology to syntax, and latterly **semantics** has become increasingly prominent. In morphology, syntax, and typologically oriented studies, perhaps especially in 'grammatical semantics,' semantics has made a considerable contribution to our understanding of verbal categories like tense or aspect, nominal categories like case or possession, clausal categories like causatives, comparatives, or conditionals, and discourse phenomena like reference and anaphora. Similarly, the study of lexical semantics and its relation to syntax, pragmatics, and cognitive linguistics has grown vastly; and it goes without saying that the study of logical semantics has developed and thrives, often in interaction with computational linguistics.

One view of **pragmatics** is that sees itself as involving the study of human language use as it is exercised in a community of social practice. The exercise is, however, not limited to verbal signs: other communicative means are also included, as becomes clear when one studies 'pragmatic acts' as well as the traditional 'speech acts.' In addition, emphasis is placed on the way communication itself is organized socially, not just as envisaged in the earlier speaker-oriented models due to Austin, Searle, and Grice, but extending also to comprise more recent advances, especially in our understanding of notions of inference and implicature, including a recent expansion into the domains of optimality theory and relevance theory. Pragmatic thinking has also advanced in what used to be called the 'hyphenated disciplines' – sociolinguistics, psycholinguistics, and so on – and more recently in the study of humans in interaction with computers, the teaching of first and second languages, literary studies, the theory of discourse, intercultural studies, cognitive research, and a host of other practically and theoretically oriented fields of study, such as conversation analysis.

Underpinning much of the study of linguistic semantics and pragmatics are issues in **philosophy.** One way of understanding the contribution of philosophy to the study of language is to see it as giving fairly sweeping answers to questions such as 'What do the parts of language (e.g., words of various kinds) mean? What do linguistic complexes, including sentences of various kinds, mean? What rules relate the part-meanings to the whole meanings?' Philosophy then goes on to ask: 'What are we talking about when we talk about meaning? What kind of thing is a linguistic rule? What form should the statement of a linguistic rule take, including especially a semantic rule?' We can then enquire into the potential implications for philosophy itself of the answers to these questions – for example, the implications of linguistic arguments for anti-realism for

metaphysics, of the discussion of language rights for ethics, of linguistic notions relating to mentalese or concepts for philosophy of mind, or of issues relating to non-standard logics or notions of logical form for logic.

The study of discourse is another expanding area of linguistic enquiry. As a general term, 'discourse' applies to both spoken and written language, and spoken and written discourse have crucial characteristics in common. The recent explosion of language corpora of all kinds and the tools to analyze them make this a burgeoning area of linguistic investigation. The linguistic traditions of the study of written and spoken discourse are different, however, and this is reflected in ELL2 by focusing on written and spoken discourse in separate sections and devoting a suite of sections to the discourse of particular genres.

Text analysis and stylistics concerns aspects of written discourse with particular emphasis on stylistics. A text is clearly more than a random set of utterances: it shows connectedness, and a central objective is to characterize this connectedness. This could be done either through looking at overt linguistic elements and structures or by seeing connectedness as a characteristic of the mental representation rather than of the text itself. This section explores both these approaches. It also considers various features of text, metaphor, and figures of speech in general and the properties of different text genres, and contains articles on stylistics and literary theory.

Since ELL1, research on **spoken discourse** has brought new and interesting insights to the broader field of linguistics through the analysis of stretches of spontaneous spoken language produced in more natural contexts. This has also pushed forward the awareness that new models for describing and interpreting speech processes are required in phonetics, in syntax, and in the broader domain of textual relations. Although the sentential and extra-sentential syntax of spoken discourse has always been part of grammars of languages with a predominant oral dimension, only recently has it gained momentum as an autonomous subject, interesting per se, especially with respect to those languages with a long history of written and spoken dimensions running in parallel or influencing each other. Detailed descriptions of the syntax and discourse of individual spoken languages have brought into focus the differences between written and spoken structures and opened a theoretical debate over the nature of such differences and the best models to deal with them. In the online version, some of the phonetic and phonological characteristics of spoken language are illustrated by audio files.

Law and language addresses issues and problems that arise from the nature of the language used in the legal system, and since the law is an overwhelmingly linguistic institution, language is implicated in many of the issues and problems associated with the legal system. An obvious issue is that the written technical language of the law is extraordinarily complex and can be virtually impossible for non-legal specialists to understand. Spoken legal language can similarly raise social issues since some social groups may not understand the language and culture of the law and may be disadvantaged as a consequence. Applied forensic linguists addresses issues and problems in the legal system that are language based, attempting to describe, and where possible explain, those features that distinguish the language used in legal settings from everyday language.

The mass media increasingly influence the way we understand other societies and cultures and the section **media and language** follows contemporary debates about the nature of media language itself as it changes in relation to changing industrial and social pressures. It notes the increasing use of conversational style by journalists and interviewers in traditional media, and explores the growing influence of emerging technologies, the most obvious of which are related to internet communication channels with enhanced opportunities for audience interactivity.

Politics and language deals with different aspects of the relation between language and politics, notably different approaches to the analysis of 'political language' in its broadest sense. Research in this area received an impetus in the latter half of the past century with the analysis of National Socialist language as an important starting point. There is also considerable research into 'language policies and language planning' more generally. This section concerns itself not only with political rhetoric in the 'classic' tradition but also with recent work involving new analytical methodologies, particularly with respect to multimodality and the impact of the visual.

Religion and language looks at 'religious language' in its wide range of manifestations. The scriptures of all religions show a vast range of genres, including myth, narrative, law, prophecy, and poetry. In some religions, written liturgical forms are normally elevated in style, sometimes poetic, often veering toward the archaic; statements of doctrine and academic theological writings share features with scientific writing such as consistent use of technical vocabulary, while the language used in private prayer may be more likely to reflect the usage of everyday language. Particular modalities of religious activity may exhibit their own stylistic features. In common parlance, 'religious language' is often taken to mean liturgical language. However, in scholarly contexts the term is nowadays often used to cover both discourse about religion (including academic theological writing and statements of doctrine) and its relation to other types of discourse, and discussion of how religious texts should be interpreted.

Medicine and language focuses on two aspects of medical discourse: the oral and the written. The oral papers address issues related to patient–doctor communication (e.g., illness narratives, psychiatric interviews, medical conferencing, medical specialty encounters). Most articles that deal with the written aspect of medical discourse focus on the medical scientific 'research article' considered both from a generic, diachronic and a synchronic perspective. Some of these articles also analyze the socio-historical construction of medical discourse and the evolution of the socio-pragmatic phenomenon of hedging.

Psycholinguistics is concerned with understanding mental processes, so psycholinguists are interested in how linguistic units are processed and represented internally. The psycholinguistics section reviews the field since it emerged as a distinct discipline in the 1950s and reviews the major research topics over the last 50 years – sentence processing, speech production, speech recognition, discourse processing, reading, visual word recognition, dialogue, and gesture – and the research methods used, from experimental to computational modeling of language processes.

Language acquisition surveys the timetable of language development from infancy to adulthood, dealing with infant sensitivity to linguistic form, and the development of phonology, words, morphology, grammar, pragmatic, and metalinguistic skills. Other articles covers the topics of bilingual development, the acquisition of sign language, and some atypical developments. The articles deal with relevant theoretical issues, relating them to other sections.

The **Brain and language** section covers current developments in research on the brain and language processing. It includes accounts of studies of language disorders and language impairments from speech motor processes to narrative and discourse impairments and their remediation. It is also concerned with the effect on language of specific neurological diseases such as schizophrenia, Williams' syndrome, autism, Asperger's syndrome, etc. And it describes recent developments in neuropsychology, psychiatry, neurology, and neurosurgery insofar as they affect language and current models of language processing.

Cognitive science assumes the human mind to be a computational device containing representations and seeks to develop cognitive models of language processing. It draws on concepts from artificial intelligence and computer science, linguistics, psychology, philosophy, the neurosciences, and anthropology.

The section on **computational linguistics and natural language processing** reflects the fact that the past 10 years has seen the explosive growth of the World Wide Web, electronic mail, Internet publishing, and the cellular phone used for fun, business, and academic enquiry. This mass connectivity has greatly increased the demand for software tools and appliances for processing unstructured and semi-structured natural language text, and has led to a consequential growth in information accessories. Web browsers, search engines, and personal digital assistants have become ubiquitous and commonplace, and new modes of behavior have developed around such everyday activities as purchasing goods, accessing entertainment, and conducting business. There have also been considerable developments in the field of machine translation. This has led to developments in language technology and has been facilitated by two technical breakthroughs. The first is conceptual, and represents a new emphasis upon empirical approaches to language processing that rely more heavily upon corpus statistics than linguistic theory (often referred to as corpus linguistics). The second is computational, and consists of more powerful, networked machines that are capable of processing millions of documents and performing the billions of calculations that the statistical profiling of large corpora requires. This section discusses these new application areas and some recent advances.

While the previous section is largely concerned with the manipulation of text, the **speech technology** section is concerned with the computational processing and generation of speech. It thus focuses on issues concerned with the computer understanding of speech, such as speaker recognition, the computer generation of speech, and applications surrounding these.

Translation is another rapidly expanding academic field of study, which now includes a substantial body of theoretical writing. This draws on insights from a variety of related disciplines: philosophy, linguistics, literary studies and criticism, stylistics, sociology, anthropology, psychology, and computational linguistics, and, increasingly, it feeds insights back into those other disciplines. There are a number of different approaches to translation, including linguistic approaches, philosophical approaches, cultural/gender-oriented approaches, the relevance theoretic approach, Skopos theory, functional approaches, and the so-called descriptive approach, each of which adopts a particular point of view of the areas referred to above. In addition, there are well-established translation theoretic notions such as translational equivalence, translation purpose, translation functions, the unit of translation, and, of course, the concept of translation itself. There is also an increasingly finely defined field of interpreting studies, aspects of which hold particular relevance for a work dedicated to linguistics. This field also covers sign language interpreting.

The section on **sign languages** shows the central place language has in human culture since it demonstrates that in any human social group the emergence of language is inevitable, and if the auditory channel is not available, language materializes in the manual-visual modality instead. Although transmitted in a radically different physical modality, natural sign languages share key linguistic properties with spoken languages, for example, the existence of both a meaningless 'phonological' level and a meaningful morpho-syntactic level of structure, derivational and inflectional morphology, and syntactic recursion. Sign languages are acquired by children without instruction and according to the same timetable as spoken languages, and they are also controlled primarily by the left hemisphere of the brain. Yet modality does matter, and comparing languages in each modality allows us to isolate the effect of the physical medium on the content, structure, and organization of natural language, be it spoken or signed. In the online version there are illustrations of signing.

Linguistic theory needs constant refreshment from language data, and it would be surprising if an encyclopedia on languages and linguistics did not pay major attention to the **languages of the world.** There are, of course, abundant language data in the articles themselves, but in addition, the languages of the world section presents a set of 400 articles on specific languages or language families. The 15th (2005) edition of *Ethnologue* identifies 7299 languages. Given this large number, the encyclopedia can clearly present only a sample. We have tried to include articles on languages from all the major language families. Each language article gives a brief description of the language and its speakers, plus any known or hypothesized genetic relationships, and highlights interesting phonological, semantic, or syntactic features. In the online version many of the articles are accompanied by video or audio files.

There is an alphabetical list of these languages in the subject classification, and appended to the article 'Classification of Languages' is a taxonomy of all the languages distributed into their 'families.' The article itself explains the basis of the classification. There are articles on a number of languages now no longer spoken and numerous articles on endangered languages. The language articles are all cross-referenced to the relevant article in the countries and languages section that describes the language situation in the country where the language is spoken. Through this cross-referencing, readers are referred to a map showing the geographical distribution of the particular language.

The section **countries and languages** contains a set of articles outlining the language situation in most of the countries of the world. The aim is to provide up-to-date information about the languages spoken in the country, about numbers of speakers for each language, how these languages are used in society and communication, and about social, cultural, or political aspects that are of interest for both general and specialist linguistic audiences. This information comes from public sources, such as censuses or education statistics, from the specialist literature, or from personal experience in the country. Where possible we have found authors with first-hand knowledge of the countries concerned, and in these cases the articles are signed. For a few countries and territories this has not proved to be possible, and for those we have been fortunate to be able to rely on a small 'editorial team': Lutz Marten (SOAS); Boban Arsenijević (University of Leiden), Mark de Vos (University of Leiden), Nancy Kula (University of Leiden), Anikó Lipták (University of Leiden), Anna McCormack (SOAS), and Laura Mutti (SOAS). These articles are unsigned. Many of the articles in this section are associated with multimedia annexes in the online version of ELL2.

Ethnologue has kindly permitted us to reprint their **language maps.** These are collected in the last volume. Articles in the countries and languages section are associated with one or more of these maps. Individual languages are cross-referenced to countries and thence to the relevant language map.

All the languages mentioned in the articles in the countries and languages section together with the languages noted in the current edition of *Ethnologue* are collected into a **list of languages**. This list records the name of a language, alternative names, a brief summary of its genetic affiliation, a list of the country or countries where it is spoken, and the number of speakers. The identification of a 'tongue' as a distinct language is a well-known difficulty; naming languages is another. Both issues are explored in the article 'Ethnologue.' In ELL2 we have decided to standardize on Ethnologue names to achieve consistency across the encyclopedia since there is no other source of information about languages that is as comprehensive. In the list of languages, Ethnologue names are used as headwords. In language articles, languages appear under the name preferred by the author, and typically where this differs from the Ethnologue name there is also a 'dummy entry' under the Ethnologue name cross-referring to the entry under the non-Ethnologue name. This is because even though a particular author may prefer not to use an Ethnologue name, there will be other scholars who do use Ethnologue names (and indeed there could be other articles in the encyclopedia that use them), so both names need to be included in the encyclopedia somewhere. In the list of languages, languages are also identified by the three-letter language identifiers of the Draft International Standard codes of ISO/DIS 639–3, identifiers that are also used in Ethnologue.

Lexicography is a discipline with a long history in most cultures. Typically, it aims at breadth of coverage rather than depth. Depth is achieved in the related discipline of lexicology, through detailed studies of key elements in the lexicon. The aim of lexicography is the systematic collection and explication of 'all' the words of a language (more strictly speaking, all the lexical items of a language, including idioms, multi-word expressions, and bound morphemes, as well as individual words). This encyclopedia contains articles on the history, current state of the art, and available lexicographic resources of the world's major languages, complementing the corresponding articles on individual languages and language situations. In the past two decades, the practice of lexicography has been transformed by the evidence of usage that is now to be found in large electronic corpora, so that the traditional historical-cultural focus of lexicography is beginning to be matched by empirically well-founded accounts of the dynamic nature of the lexicon and the relationship between word meaning and word use. This section also contains articles on some key aspects of onomastics.

Writing systems traces the history of writing and writing systems throughout the world's languages. It traces the development of writing in Mesopotamia, the Aegean, and Asia and the development of Chinese, Japanese, and Korean scripts and of Mesoamerican writing systems. The section also has a set of articles on general issues to do with notation of various kinds and on the mechanics and aesthetics of writing.

Applied linguistics is an interdisciplinary area that attempts to describe, explain, and work out solutions to social issues and problems related to real-world language problems, the more prominent among them associated with language learning and teaching. In this context it has long been interested in theoretical issues and also in the practicalities surrounding learning and teaching. The section contains a set of regional studies of these issues around the world. This develops into a concern for a wide range of issues relating to language and language use in general: bi- and multilingualism, language contact, language policy and planning, and the professional and occupational use and misuse of language. In recent years, research in applied linguistics has also interested itself in general issues in the nature and psychology of second language acquisition and the contribution this can make to linguistic theory in general. Applied linguistics also contributes to research in corpus linguistics, lexicography, literacy, sociolinguistics, and teacher preparation.

The starting point of **educational linguistics** is always the practice of education, and the focus is squarely on the role of language in learning and teaching. Educational linguistics has been characterized as 'transdisciplinary' in that it brings together aspects of linguistics with the research tools and methodologies of other social sciences, most often anthropology, psychology, and sociology, to investigate the totality of issues related to language acquisition, language use, and sociolinguistic context in formal and informal education. This section explores these issues and particularly the different approaches to language in education developed in Britain, Australia, and America.

The field of **sociolinguistics** is a broad one that focuses on the use of language in its social contexts. These contexts may be physical, or at least, institutional, as in the study of domain-related registers or styles of language; interactional, as in the study of the dialogic nature of speech; or social, pertaining to characteristics of individuals or groups along the lines of gender, class, ethnicity, age, etc. A central concern of the field is how language varies according to these contexts. But some studies also focus on how language itself forms part of the social context, emphasizing that language is not just reflective or characteristic of certain contexts, but may help shape, sustain, and reproduce those contexts. Other concerns of this field include the cultural dimensions of language and issues pertaining to individual and social identity; many of these issues are also discussed, from another angle, in the pragmatics section.

The **variation and language** section is concerned with variation within speech communities with shared linguistic systems as they are affected by social norms of use and interpretation and by social attitudes toward language. Dialect variation has long been the subject of academic exploration, joined in recent years by studies of the effects on language use of age, sex and gender, ethnicity, and other variables. The relevance of such studies for social science has long been clear, and there is an increasing appreciation of the relevance of such variationist studies for linguistic theory more generally. A number of the articles focus on methods for studying variation, and we hope these will be useful practical guides for readers undertaking their own research. The section also includes a set of articles on variation in different language communities.

Linguistic anthropology is the study of language in culture, and of linguistic practices as part of culture. The field of linguistic anthropology takes linguistic practices to be culturally significant actions that constitute social life. Indeed, the situated use of language is the exemplary case of how culture, as a meaning-making process, constructs and shapes the social world. That world is invariably saturated with contrasting values and contested interests, with opposed political positions and identities, with variable access to resources and power. Linguistic anthropology examines the role of discursive interaction – and the semiotic processes on which it relies – in

making and mediating those differences. Aspects of context enter into this process through the linguistic form itself, as it signals presuppositions and projections that are called into play during discursive interaction. Presuppositions can draw on any cultural realm: categories of contrasting selves and identities, notions of truth, space, time, cosmological order, nature, morality. Such notions are invariably linked to culturally specific conceptions about language itself. These are metadiscourses about language and its role in social life and thus relate to advances made in the study of discourse and pragmatics-related areas.

During the 19th century the dominant mode of study of languages was **historical and comparative,** and the ELL2 section both expounds the historical bases of the discipline and outlines new directions in thinking about the subject. Central to the discipline is, of course, the notion of language change, and there are articles on both the traditional approach to such matters and more recent developments in thinking about phonological, morphological, and syntactic change. The reconstruction of previous stages in the development of languages forms part of the discipline's basic methodology, and the section includes articles on a variety of proposed proto-languages.

There are few societies in which there has been no speculation about the nature and origin of language. The section on schools and traditions in the **history of linguistics** section testifies to this. This section includes articles on the major traditions of linguistic enquiry worldwide, including those of Babylon, China, India, Japan, Greece, and Rome, as well as accounts of linguistic thought and practice from the Middle Ages up to the 20th century.

The history of linguistics is closely tied to the lives of individual scholars, and for this reason ELL2, like ELL1 before it, has a substantial section of 700 **biographies.** These cover lives from the times of the earliest records and from all parts of the world. In this area, the selection of names is far from easy, and the issue is particularly difficult where it concerns living linguists. We have tried to be adequately representative and have taken particular care to record the contribution to linguistic scholarship of women linguists. Many of the biographies are accompanied by a portrait, especially in the online version.

The **glossary** is intended as a quick reference point for terminology met within the body of the encyclopedia.

The articles are arranged in alphabetical order. All are signed except for a few in the countries and languages section that were compiled by the editorial team as explained above. In order to assist those who wish to pursue a particular subject beyond the individual article, all but the very shortest articles have a **bibliography** that carries bibliographical details of all works referred to in the article itself and, where this is relevant, items for further reading. In preparing these bibliographies, authors have been asked to give preference to works that are reasonably accessible, to books rather than to articles, and in general to publications in European languages, particularly English, the language of the encyclopedia. Where relevant, the bibliography also lists URLs of pertinent websites. All but the shortest articles contain **cross-references,** usually at the end of article, to other articles in the encyclopedia. In the last volume there is a **subject classification**, which groups articles together according to their subject matter, and a general **subject index.**

ELL2 owes a special debt of gratitude to Diane Cogan (Publishing Director, Social Sciences), Chris Pringle (Publisher, Social Sciences) and Sarah Oates (Publishing Editor, Language and Linguistics), who conceived the idea of a new edition of the encyclopedia and drove the project through the initial stages of getting Elsevier approval. Bob Donaldson (Developmental Manager), Mark Sheehan (Local Application Manager), and other members of the Social Sciences editorial team contributed to the 2004 planning meeting, which Jo Gartside (Secretary, Social Sciences) organized the great efficiency. As the project grew, Natalia Kennedy (Developmental Editor) and her team were responsible for the complexities of contracting authors and managing the inflow of manuscripts; Stacey Penny (Senior Production Project Manager) and her team were responsible for seeing articles into proof and subsequently into the final form of the encyclopedia; Ann-Helen Lindeholm (Senior Marketing Manager) has been in charge of publicity; and there are many others in the Elsevier Major Reference Works team whose professional skills have been invaluable.

Keith Brown

PUBLISHING HISTORY

The first edition of the *Encyclopedia of Language and Linguistics,* edited by Ron Asher, was published by Elsevier under the Pergamon imprint in 1993. It received universally enthusiastic reviews and has been without question the outstanding reference work in its field for over a decade.

Choice, 1994

The editors intend their work simply to be the most authoritative, up-to-date, comprehensive, international reference source in the field. There can be little doubt of its having achieved that goal. It owes its authority to its distinguished editorial boards and the 1,000 specialists who contributed articles . . . .

Wilson Library Bulletin, 1994

This does exactly what a specialized encyclopedia should . . . Readable, comprehensive, and current, The Encyclopedia of Language and Linguistics will be the field's standard reference for a generation.

Journal of Linguistics, 1994

This is now the definitive and indispensable scholarly reference publication, on all branches of linguistics . . . .

Journal of Pragmatics, 1994

. . . an ambitious and much-needed work, surpassing in its extent as well as in quality all previous encyclopedias . . . makes its treatment of language and linguistics complete par excellence, and interdisciplinary to an extent which has never been achieved before.

Diachronica, 1994

. . . the coverage of the field is impressive, especially if compared to similar recent encyclopedic works of so-called "state-of-the-art" surveys of linguistic science.

Excerpta Medica, 1995

. . . the most comprehensive and ambitious work of its kind ever produced . . . .

Computational Linguistics, 1994

Since it arrived, it has been used as an oracle whenever a linguistic question arose that I couldn't answer from my own knowledge . . . . Everyone who is a linguist of any flavor at all should have a copy of this encyclopedia . . . .

Times Literary Supplement, 1995

> The want of a proper encyclopedia of language studies has been felt for many years. It need be felt no longer. The lacuna has now been filled by these ten volumes from Pergamon Press, and – it must be said straight away – filled more solidly and satisfactorily than one had any right to expect. Every serious university library should have a copy, or else its students have a reasonable case for saying that the librarian and library committee ought to be sacked en masse.

Pergamon Press, in the form of its subsidiary, Aberdeen University Press, began discussions about the encyclopedia in the mid-1980s under the directorship of Colin MacLean. Ron Asher was called upon for his expertise in the discipline; he shared Pergamon's view of the importance of extensive coverage of both the core areas of linguistics and their relationships with other disciplines. The fundamental, and ambitious, aim was to be as interdisciplinary as possible. This approach, as the reviews attest, is what has truly set the encyclopedia apart from its competitors over the years.

In 1988, under the chairmanship of Ron Asher, a three-day meeting of 30 specialists took place in Jersey. As a result of this meeting, both the Honorary Editorial Advisory Board and the Executive Editorial Board were created. Seumas Simpson assumed the role of Coordinating Editor. The Executive Editorial Board was composed of 34 experts in their field who each took responsibility for a specific subject area. Their aim was to commission articles that could be understood by experts and non-experts alike, to ensure that the contributors were international (75 countries were represented by authors), and to ensure that there were no gaps in coverage. Ron Asher and Seumas Simpson dedicated themselves to the latter in particular, and with the input from the Honorary Editorial Board, under the chairmanship of Angus McIntosh, they created the most comprehensive reference work in its field.

The first edition continued to sell until its final copy was dispatched in 2004. Although the second edition builds on the foundations laid by the first as far as its intellectual approach is concerned, it is an entirely new work in terms of content and editorial direction. The second edition, under the editorship of Keith Brown, takes the fullest possible account of advances in the discipline in the past 10 years and allows new authors to bring additional insights to enhance the coverage the original articles gave to their topics. The second edition, though entirely new, is the intellectual successor to the first edition.

Sarah Louise Oates
Publishing Editor, Language & Linguistics
Elsevier

EDITOR-IN-CHIEF

Keith Brown, *University of Cambridge, UK*

Keith Brown, ELL2 Editor-in-Chief, read English at Cambridge, joined the British Council, and worked in Uganda. He then taught at the University College of Cape Coast in Ghana before moving to Edinburgh, where he took his Ph.D. in linguistics and subsequently taught in the Department of Linguistics. In 1984 he moved to the University of Essex, where he was Research Professor in the Department of Linguistics, and then to the University of Cambridge, where he was Senior Research Fellow in the Research Centre for English and Applied Linguistics. He is now an Associate Lecturer in the Faculty of English at Cambridge. He has held visiting professorships at the Universities of Heidelberg, Vienna, and Düsseldorf. From 1990 to 1994 he was President of the Linguistics Association of Great Britain, and he has been a member of Council of the Philological Society since 1998. He is Chairman of the Linguistics Committee of the Subject Centre for Languages, Linguistics and Area Studies. He is co-editor of *Transactions of the Philological Society* and sits on other editorial boards. He is author of *Linguistics Today* (Fontana, 1984) and co-author, with Jim Miller, of *Syntax: A Linguistic Introduction to Sentence Structure* and *Syntax: Generative Grammar* (Hutchinson, 1981). He was syntax editor for the first edition of the *Encyclopedia of Language and Linguistics* and was joint editor, with Jim Miller of *A Concise Encyclopedia of Linguistic Theories* and *A Concise Encyclopedia of Grammatical Categories* (Pergamon Press, 1997 and 1998). He was joint editor of *Common Denominators in Art and* Science (Aberdeen University Press, 1983) and *Language, Reasoning and Inference* (Academic Press, 1986).

COORDINATING EDITORS

Anne Anderson, *University of Glasgow, Scotland*

Professor Anne H. Anderson, M.A. Ph.D. O.B.E, is a psycholinguist interested in communication, notably in dialogue and the impacts of new communication technologies on communication. Her research over several years has investigated how people communicate in dialogue and how communication systems do or do not replicate the advantages of face-to-face interactions. She has held many research grants on communication and the impacts of communication technologies and has published widely in the scientific literature with over 45 major scientific publications on human communication.

Professor Anderson was a principal investigator in the Human Communication Research Centre funded from 1990 to 2000 by ESRC. She has held a chair in psychology since 1997 at the University of Glasgow. The department was awarded the highest grade, a 5*, in the recent Research Assessment Exercise. From 1995 to 2000 she was director of the ESRC Cognitive Engineering programme, an initiative that funded projects across the UK on topics concerned with people and information technology. In 2000 she was appointed director of the People at the Centre of Information and Communication Technologies (PACCIT) programme, which is funded by ESRC, EPSRC, and the DTI and seeks to build research collaborations between universities and industry. She is also a section editor for Psycholinguistics.

Laurie Bauer, *Victoria University of Wellington, New Zealand*

Laurie Bauer was born in the north of England, attended Edinburgh University, from where he got a Ph.D. in 1975, and since then has worked in Odense, Denmark, and Wellington, New Zealand. He holds a personal chair in linguistics at Victoria University of Wellington. He has published widely in the fields of morphology and international varieties of English (particularly New Zealand English), and has also published in the fields of phonetics, language change, and dialectology. His most recent books are *Morphological Productivity* (CUP, 2001) and *An Introduction to International Varieties of English* (Edinburgh UP, 2002); a second edition of his *Introducing Linguistic Morphology* is currently in press. He is on the editorial boards of *Linguistics*, the *Yearbook of Morphology*, and *English World-Wide*, as well as the editorial boards for three book series. He was the subject editor for Morphology in the first edition of the encyclopedia and is also a section editor for Morphology.

Margie Berns, *Purdue University, USA*

Margie Berns is a Professor of English Language and Linguistics and Director of the Program in English as a Second Language at Purdue University (Indiana, USA). Her areas of specialization are English in the global context, language policy and planning, and second language studies. Among her publications on these and related topics are *Contexts of Competence: Social and Cultural Considerations in Communicative Language Teaching* (Plenum, 1990), *Initiatives in Communicative Language Teaching* (Addison Wesley, 1984), and

Initiatives in Communicative Language Teaching II (Addison Wesley, 1987). Articles and reviews have appeared in *TESOL Quarterly, World Englishes, International Journal of Applied Linguistics*, and *English Today.* A member of the International Association for World Englishes (IAWE), International TESOL, and the American Association for Applied Linguistics (AAAL), she has served in such capacities as IAWE Conference and Program Chair, and AAAL President, Conference and Program Chair, and Member-at-Large. She is also a section editor for Applied Linguistics.

Keith Brown, *University of Cambridge, UK*

Keith Brown, ELL2 Editor-in-Chief, read English at Cambridge, joined the British Council, and worked in Uganda. He then taught at the University College of Cape Coast in Ghana before moving to Edinburgh, where he took his Ph.D. in linguistics and subsequently taught in the Department of Linguistics. In 1984 he moved to the University of Essex, where he was Research Professor in the Department of Linguistics, and then to the University of Cambridge, where he was Senior Research Fellow in the Research Centre for English and Applied Linguistics. He is now an Associate Lecturer in the Faculty of English at Cambridge. He has held visiting professorships at the Universities of Heidelberg, Vienna, and Düsseldorf. From 1990 to 1994 he was President of the Linguistics Association of Great Britain, and he has been a member of Council of the Philological Society since 1998. He is Chairman of the Linguistics Committee of the Subject Centre for Languages, Linguistics and Area Studies. He is co-editor of *Transactions of the Philological Society* and sits on other editorial boards. He is author of *Linguistics Today* (Fontana, 1984) and co-author, with Jim Miller, of *Syntax: A Linguistic Introduction to Sentence Structure* and *Syntax: Generative Grammar* (Hutchinson, 1981). He was syntax editor for the first edition of the *Encyclopedia of Language and Linguistics* and was joint editor, with Jim Miller of *A Concise Encyclopedia of Linguistic Theories* and *A Concise Encyclopedia of Grammatical Categories* (Pergamon Press, 1997 and 1998). He was joint editor of *Common Denominators in Art and* Science (Aberdeen University Press, 1983) and *Language, Reasoning and Inference* (Academic Press, 1986).

Jim Miller, *University of Auckland, New Zealand*

Jim Miller is Professor of Cognitive Linguistics in the University of Auckland. Before going to Auckland he was Professor of Linguistics and Spoken Language in the Department of Theoretical and Applied Linguistics in the University of Edinburgh. He graduated from the University of Edinburgh in 1965 with a degree in Russian with French, and his first and abiding research interests are aspect, case and transitivity, and Russian. A large part of his first 20 years in linguistics was devoted to the study of various models of generative grammar. In the late 1970s he and Keith Brown carried out an investigation into the syntax of Scottish English. This work led him to investigate the syntax and discourse organization of spontaneous spoken language (Russian and French as well as English) and to the relationship between spoken and written language, literacy, language and education, language and politics and language, and identity. Regina Weinert and he published *Spontaneous Spoken Language* in 1998. He is currently working on speaking, writing, and language acquisition and on spoken language, non-standard language, and typology.

Graeme Hirst, *University of Toronto, Canada*

Graeme Hirst (Ph.D., Brown University, 1983) is a Professor of Computer Science at the University of Toronto, specializing in computational linguistics and natural language processing. Hirst's research has covered a broad but integrated range of topics in computational linguistics, natural language understanding, and related areas of cognitive science. These include the resolution of ambiguity in language understanding; the preservation of author's style in machine translation; recovering from misunderstanding and non-understanding in human–computer communication; and linguistic constraints on knowledge-representation systems. His present research includes the problem of near-synonymy in lexical choice in language generation; computer assistance for collaborative writing; and applications of semantic distance in intelligent spelling checkers. From 1994 to 1997, Hirst was a member of the Waterloo-Toronto HealthDoc project, which aimed to build intelligent systems for the creation and customization of health-care documents. Hirst is a member of the editorial boards of *Machine Translation* and *Computational Linguistics,* and has been book review editor of the latter since

1985. He is the author of two monographs: *Anaphora in Natural Language Understanding* (Springer-Verlag, 1981) and *Semantic Interpretation and the Resolution of Ambiguity* (Cambridge University Press, 1987). He is the recipient of two awards for excellence in teaching. He has supervised post-graduate students in more than 35 theses and dissertations, four of which have been published as books. He is also a section editor for Natural Language Processing and Machine Translation.

SECTION EDITORS

Animal Communication – Marc Naguib, *University of Bielefeld, Germany*

Marc Naguib is Associate Professor at the University of Bielefeld, Germany. He received his Ph.D. in 1995 at the University of North Carolina at Chapel Hill. His research addresses mechanistic and functional questions in animal communication, focusing on vocal communication in song birds, with interests ranging from song development to the evolution of signal structures and signaling strategies. He has published numerous research articles on auditory distance perception of song birds under natural field conditions, categorization of signals, and strategies of vocal interactions in dyadic interactions and communication networks. He is Associate Editor for *Advances in the Study of Behaviour* and on the Editorial Board of *Animal Behaviour.*

Applied Linguistics – Margie Berns, *Purdue University, USA*

Margie Berns is a Professor of English Language and Linguistics and Director of the Program in English as a Second Language at Purdue University (Indiana, USA). Her areas of specialization are English in the global context, language policy and planning, and second language studies. Among her publications on these and related topics are *Contexts of Competence: Social and Cultural Considerations in Communicative Language Teaching* (Plenum, 1990), *Initiatives in Communicative Language Teaching* (Addison Wesley, 1984), and *Initiatives in Communicative Language Teaching II* (Addison Wesley, 1987). Articles and reviews have appeared in *TESOL Quarterly, World Englishes, International Journal of Applied Linguistics*, and *English Today.* A member of the International Association for World Englishes (IAWE), International TESOL, and the American Association for Applied Linguistics (AAAL), she has served in such capacities as IAWE Conference and Program Chair, and AAAL President, Conference and Program Chair, and Member-at-Large. She is also a section editor for Applied Linguistics.

Biographies – Kurt R Jankowsky, *Georgetown University, USA*

Kurt R. Jankowsky is Professor of German at Georgetown University, Washington, DC. He obtained an M.A. (*Staatsexamen*) in German and English, and a Dr.Phil. in German, English, and philosophy from the University of Münster. For four years he taught German language and linguistics at Poona University, India before joining Georgetown. His principal research interest is the field of Germanic linguistics, specifically the numerous dimensions of the history of language, which resulted in eight book publications and approximately 100 journal articles. He has also taught and published on semantic theory, e.g., the interrelation of language and thought, and mentored numerous M.S. theses and about 20 Ph.D. theses that specialized on various linguistic aspects. His hobbies include teaching linguistic summer courses in Tokyo and participating in international conferences, so far on five continents.

He was recently appointed Honorary President of the English Philological Society of Japan, Tokyo, and elected Fellow of the RSA, London.

Brain and Language – Harry Whitaker, *Northern Michigan University, USA*

Harry Whitaker is Professor and Head of the Department of Psychology, Northern Michigan University. His Ph.D. in linguistics (University of California at Los Angeles) was directed by the late Prof. Victoria A. Fromkin. In 1974 he founded *Brain and Language* (Elsevier) and continues as Editor; in 1982 he founded *Brain and Cognition* (Elsevier), for which he functioned as Editor through 2002. Included in books he has authored or edited are *On the Representation of Language in the Human Brain* (Linguistic Research, 1971), *Studies in Neurolinguistics,* Volumes 1–4 (Academic Press, 1976–1979), *Dyslexia: A Global Issue*. (with R. N. Malatesha; Martinus Nijhoff, 1984), *Neuropsychological Studies of Non-focal Brain Damage: Dementia and Trauma* (Springer-Verlag, 1988), *Phonological Processes and Brain Mechanisms* (Springer-Verlag, 1988), *Contemporary Reviews in Neuropsychology* (Springer-Verlag, 1988), *Agrammatism* (Singular Press, 1997), and *Handbook of Neurolinguistics* (with B. Stemmer; Academic Press, 1988). His current editorial board appointments include *Neuropsychiatry, Neuropsychology and Behavioral Neurology: A Journal of Clinical Neuroscience*, *Psychologie et Histoire*, *Journal of the History of the Neurosciences*, and *Brain and Cognition*. He is a Fellow of the American Psychological Association and past President of the International Society for the History of the Neurosciences.

Cognitive Science – Jon Oberlander, *University of Edinburgh, Scotland*

Jon Oberlander is Reader in Cognitive Science at the University of Edinburgh and Director of the Informatics Graduate School at Edinburgh. He studied philosophy at Cambridge and cognitive science at Edinburgh. His research lies at the intersection of computational linguistics and cognitive science, and covers both automatic discourse generation and diagrammatic reasoning and communication. He has a particular interest in individual differences in communicative strategies and technologies for catering for them.

Computational Linguistics – Allan Ramsay, *University of Manchester, UK*

Allan Ramsay is a Professor in the School of Informatics in the University of Manchester where he works on developing systems that can understand natural language. Such systems have a wide range of applications, from machine translation through information extraction to computer-based tools for language learners. His current research covers development of grammars for a range of languages (currently English, French, German, Spanish, Greek, Arabic, and Persian). This work is underpinned by a novel approach to the problems raised by 'free word order' languages. It also covers application of theorem proving techniques for higher-order logics in order to extract the information that is implicit in what someone actually says or writes. This involves the development of appropriate inference techniques, since higher-order logic is extremely difficult to work with, and of appropriate meaning representations.

Countries and Language – Lutz Marten, *School of Oriental and African Studies, University of London, UK*

Lutz Marten studied English language, philosophy, African studies, and linguistics in Hamburg and London. He received his Ph.D. in linguistics in 1999 from the School of Oriental and African Studies, University of London, where he is now a lecturer in Southern African Languages.

His main research interests are linguistic theory (syntax, semantics, pragmatics, formal models of interpretation), African languages and linguistics, and language and society. He has conducted fieldwork in East, Central, and Southern Africa, working on Swahili, Luguru, Bemba, Herero, and other Bantu languages. He is involved in the Dynamic Syntax project and is working together with Ruth Kempson (King's College London) on an AHRB-funded project on pronominal reference and agreement in Bantu and Romance languages.

His publications include *At the Syntax-Pragmatics Interface: Verbal Underspecification and Concept Formation in Dynamic Syntax* (2002, OUP), *A Grammatical Sketch of Herero* (with Wilhelm Möhlig and Jekura Kavari, 2002, Köppe), *Colloquial Swahili* (with Donovan McGrath, 2003, Routledge), and *The Dynamics of*

Language (with Ronnie Cann and Ruth Kempson, 2005, Elsevier). He is a member of the editorial board of the *Journal of African Languages and Linguistics*, and he is the Honorary Secretary of the Philological Society. His homepage, with more information, can be found at http://mercury. soas.ac.uk/users/lm5.

Education and Language – Bernard Spolsky, *Bar-Ilan University, Israel*

Bernard Spolsky is Professor Emeritus in the English Department at Bar-Ilan University and Senior Associate at the National Foreign Language Center at the University of Maryland. Educated in New Zealand and with a Ph.D. from Université de Montréal, he taught at the Hebrew University of Jerusalem, McGill University, Indiana University, and the University of New Mexico (where he was Professor of Linguistics, Anthropology and Elementary Education and Dean of the Graduate School) before his appointment at Bar-Ilan in 1980, where he also served as Dean of Humanities and Director of the Language Policy Research Center.

His research has been in applied and educational linguistics (including language testing), sociolinguistics, and language policy. He was a founding co-editor of *Applied Linguistics* and is Editor-in-Chief of *Language Policy.* His books include *Conditions for Second Language Learning* (Oxford University Press, 1989), *The Languages of Jerusalem* (Clarendon, 1991, with Robert Cooper), *Measured Words: The Development of Objective Language Testing* (Oxford University Press, 1995), *Sociolinguistics* (Oxford University Press, 1998), *The Languages of Israel* (Multilingual Matters, 1999, with Elana Shohamy), *Concise Encyclopedia of Educational Linguistics* (Pergamon, 1999), and *Language Policy* (Cambridge University Press, in press). He is currently preparing a compendium of national language policies.

Foundations of Linguistics – Billy Clark, *Middlesex University, UK*

Billy Clark is Programme Leader and Senior Lecturer in Communication and English Language Studies at Middlesex University. He studied English language and literature at Aberdeen and has a Ph.D. in linguistics from University College London. His research interests are in semantics, pragmatics, particularly relevance theory, philosophy of language, and stylistics. He is also a member of several groups interested in linguistics in education.

Glossary Editors – Philip Durkin, *Oxford English Dictionary, UK*

Philip Durkin studied the history of the English language and medieval literature at the University of Oxford, completing a doctorate on late Middle English prose texts and their manuscript contexts in 1994. In the same year he joined the staff of the Oxford English Dictionary. He is now Principal Etymologist at the OED, leading a team of specialist editors revising the existing etymologies in the dictionary and also preparing etymologies for newly added words. He speaks and publishes widely on etymology and historical lexicography, and has since 2000 been a member of the council of the Philological Society.

Glossary Editors – Kathryn L. Allan, *University of Salford, UK*

Kathryn L. Allan is a Lecturer in English Language at the University of Salford in Greater Manchester; previously she has lectured in the Universities of Oxford and Glasgow and worked on projects including the *Historical Thesaurus of English*, the *Scottish Corpus of Texts and Speech* and the *Middle English Grammar Project*. Her research is in the field of lexical semantics; specifically she is interested in cognitive theories of metaphor and in the interface between cognitive theories of language and traditional strands of language study.

Grammatical Semantics – Östen Dahl, *Stockholm University, Sweden*

Östen Dahl received his Ph.D. in Slavic languages from the University of Göteborg, Sweden, where he then taught linguistics for about 10 years. Since 1980, he has been Professor of General Linguistics at Stockholm University. His early work focused on logically based approaches to grammar. Later on, his research was mainly typologically oriented with a strong interest in diachronic approaches to grammar. A focal area has been tense and aspect: in 1985, he published the monograph *Tense and Aspect Systems* (Blackwell), and he was coordinator of the Tense and Aspect group within the EUROTYP project, resulting in the edited volume *Tense and*

Aspect in the Languages of Europe (Mouton de Gruyter) in 2000. Together with Maria Koptjevskaja Tamm, he edited *The Circum-Baltic Languages: Typology and Contact* (2 volumes, Benjamins, 2002). He is a member of the Editorial Board of *Linguistics* and a consulting editor of several other journals. He is a co-author of the CUP textbook *Logic in Linguistics* and has also written textbooks in Swedish. Together with Pieter Seuren, he edited the Semantics section in ELL1.

Historical and Comparative Linguistics – Mark Hale, *Concordia University, Canada*

Mark Hale is Associate Professor at Concordia University. His research interests are diachronic linguistic methodology, with special reference to its relationship to theoretical work in phonology and syntax, Indo-European linguistics, and Austronesian (especially Oceanic) linguistics. He received his B.A. from the University of Michigan in 1976, his M.A. from Indiana University in 1980, and his Ph.D. from Harvard University in 1987. Some representative publications are "Neogrammarian Sound Change," in the *Handbook of Historical Linguistics* (Blackwell); "Marshallese Phonology, the Phonetics–Phonology Interface, and Historical Linguistics," in *Linguistic Review*; and "Diachronic Syntax," in *Syntax*.

History of Linguistics – Andrew Linn, *University of Sheffield, UK*

Andrew Linn is Professor of the History of Linguistics and Head of the Department of English Language and Linguistics at the University of Sheffield. He was educated at the University of Cambridge, where he studied English and linguistics and wrote his Ph.D. thesis on 19th-century grammar-writing and the codification of Norwegian Landsmaal. This research resulted in his 1997 book, *Constructing the Grammars of a Language: Ivar Aasen and Nineteenth-Century Norwegian Linguistics*; other books include *Standardization: Studies from the Germanic Languages* (with Nicola McLelland, 2002, Benjamins) and *Johan Storm – dhi grétest pràktikal liNgwist in dhi werld* (2004, Blackwell).

In 2006 he will be editor of *Transactions of the Philological Society*; he is former editor of the *Bulletin of the Henry Sweet Society*. He is one of the founders of the Worldwide Universities Network history of linguistics consortium. While he has published widely on topics in the history of English and Scandinavian linguistics, and on issues of historiographical theory and practice, his current principal research interests concern language reform and language policy.

Language Acquisition – Elena Lieven, *Max Planck Institute for Evolutionary Anthropology, Germany*

Elena Lieven is a Senior Scientist at the Max Planck Institute for Evolutionary Anthropology in Leipzig and a Professor in the Department of Psychology at the University of Manchester, where she is Director of the Max Planck Child Study Centre. She is Editor of the *Journal of Child Language*. Her doctoral training was at the University of Cambridge, where she also taught for four years before moving to the University of Manchester in 1979. She took up the position in Leipzig in 1998. Her research is on children's language development and, in particular, the development of grammar. Within this, she has worked on strategies for constructing multiword utterances; the relationship between these strategies and cross-linguistic variation; variations in the input that children receive and how this relates to language development; and the increasing abstraction of children's linguistic representations. She has published widely in a range of journals and edited volumes.

Languages of the World – Sarah Ogilvie, *Oxford University Press, UK*

Sarah Ogilvie is an Editor at the Oxford English Dictionary, specializing in words that have come into English from world languages (outside Europe). She is a descriptive linguist, did her graduate work at the Australian National University, and has conducted fieldwork in the Umagico Aboriginal Community. She has written a grammar and dictionary of the Morrobalama language of Cape York Peninsula, Australia, and her other publications include articles on language description, sociolinguistics, lexicography, and World English.

Law and Language – Dennis Kurzon, *University of Haifa, Israel*

Dennis Kurzon, Associate Professor in English Linguistics at the University of Haifa (Israel), attained his B.A. in Slavonic studies from Sheffield University (UK), his M.A. in linguistics from Manchester University (UK), and his Ph.D. in English linguistics from the Hebrew University of Jerusalem. He has carried out extensive research into the field of legal language, especially in pragmatics of the law and language, publishing two books on different areas: *It is Hereby Performed: Explorations in Legal Speech Acts* (1986) and *A Tale of Two Remedies: Equity, Verb Aspect and the Whorfian Hypothesis* (1998), as well as many articles. He has also examined the meaning of silence, including the meaning of a suspect's silence during police investigation in *Discourse of Silence* (1997), as well as several articles.

He has published, too, in the fields of discourse analysis, and prepositions, co-editing the book *Prepositions in their Syntactic, Semantic and Pragmatic Context* (2002). He has recently entered the field of Indian sociolinguistics, and his book *Where East Looks West: Success in English in Goa and on the Konkan Coast* was published in 2003. He is now examining the historical and sociological background to the use of scripts in India, especially in Bengal.

Law and Language – John Gibbons, *Hong Kong Baptist University, Hong Kong*

Professor John Gibbons teaches in the English Department at Hong Kong Baptist University. He has wide and varied experienced of language and law issues, including working with the New South Wales Police on their language procedures. He has worked as an expert witness in more than 30 cases. He has published widely in the field of language in the law, including *Language and the Law* (Longman, 1994), *Forensic Linguistics: An Introduction to Language in the Justice System* (Blackwell 'Language in Society' series, 2003) and, as Chief Editor, with H. Nagarajan, V. Prakasam and K. V. Thirumalesh, *Language in the Law* (Orient Longman, 2004). His most recent book (with E. Ramirez) is *Maintaining a Minority Language: A Case Study of Hispanic Teenagers* (Multilingual Matters, 2004).

He is on the editorial board of the journals *Forensic Linguistics, Journal of Multilingual and Multicultural Development,* and the *International Journal of Applied Linguistics*. He is President of the International Association of Forensic Linguists.

Lexicography – Patrick Hanks, *Berlin-Brandenburgische Akademie der Wissenschaften, Germany*

Patrick Hanks was Chief Editor of Current English Dictionaries at Oxford University Press from 1990 to 2000. Before that he was Chief Editor of Collins English Dictionaries and a Research Fellow at Birmingham University, where he was the Managing Editor for the Cobuild project. His work on computational analysis of the lexicon is well known, and he has been a visiting scientist at AT&T Bell Laboratories, Digital Equipment Corporation (Systems Research Center), the University of Sheffield, the Masaryk University in Brno, and other institutions.

He is currently working on a computational lexicology research project ("Corpus Pattern Analysis") at Brandeis University in Waltham, MA. He is also a consultant to the German Language Collocations Research Project (Electronic Dictionary of the German Language) at the Berlin-Brandenburg Academy of Sciences and to other European dictionary publishers. He has written widely on the English lexicon, also on names and naming. His latest publication is a *Dictionary of American Family Names* (Oxford University Press, New York, 2003).

Linguistic Anthropology – Michael Silverstein, *University of Chicago, USA*

Michael Silverstein (Ph.D., linguistics, Harvard, 1972) is the Charles F. Grey Distinguished Service Professor in the Departments of Anthropology, Linguistics, and Psychology, and in the Committee on Interdisciplinary Studies in the Humanities at the University of Chicago, where he has been on the faculty since 1971. He studies

language structure and function, language history and prehistory, the anthropology of language use, sociolinguistics, semiotics, language and cognition (and their development), and history of linguistics and anthropology as intellectual enterprises. His fieldwork in northwestern North America and northwestern Australia has been the basis of various descriptive, theoretical, and generalizing contributions. Professor Silverstein is also investigating language use and textuality as sites of contestation and transformation of cultural values in contemporary American society, rereading social and rhetorical theory in light of the anthropology of communication. From this last line of research, he has published a popular book, *Talking Politics: The Substance of Style from Abe to "W."* (Prickly Paradigm Press, 2003).

Media and Language – Susan McKay, *University of Queensland, Australia*

Susan McKay has taught in the School of English, Media Studies and Art History (formerly the Department of English) at the University of Queensland since 1989. She is co-author (with Lloyd Davis) of *Structures and Strategies: An Introduction to Academic Writing* (1996), and has published papers on a range of media representations. She holds a degree in pharmacy (as well as a B.A. and Ph.D. in English) and has used this health background, together with her academic interest in language in the media, in much of her recent research. She has worked on media representations of health issues (including breast cancer and aging). In 2001–2002, she was part of a task force formed by the International Association of Language and Social Psychology to review aspects of research into language and communication in adolescence. She is currently investigating the discursive frameworks used in the media for men's health issues.

Medicine and Language – Françoise Salager-Meyer, *Universidad de los Andes, Merida, Venezuela*

Françoise Salager-Meyer was born in France, attended the University of Lyon, from where she got a M.A. in Russian language and literature, and later attended the University of Texas at Austin (USA), from where she got a Ph.D. in 1977. Since then, she has worked at the University of the Andes (Mérida, Venezuela) and at several Spanish universities as a visiting scholar. She has published widely in the field of scientific (mainly medical) discourse analysis, with over 60 major scientific publications. She is on the editorial boards of *English for Specific Purposes: An International Journal, The Journal of Research in Reading, Reading in a Foreign Language, The ESPecialist,* and other major journals in the field. She created the Research Group on Scientific Discourse Analysis, which she is currently coordinating.

Morphology – Laurie Bauer, *Victoria University of Wellington, New Zealand*

Laurie Bauer was born in the north of England, attended Edinburgh University, from where he got a Ph.D. in 1975, and since then has worked in Odense, Denmark, and Wellington, New Zealand. He holds a personal chair in linguistics at Victoria University of Wellington. He has published widely in the fields of morphology and international varieties of English (particularly New Zealand English), and has also published in the fields of phonetics, language change, and dialectology. His most recent books are *Morphological Productivity* (CUP, 2001) and *An Introduction to International Varieties of English* (Edinburgh UP, 2002); a second edition of his *Introducing Linguistic Morphology* is currently in press. He is on the editorial boards of *Linguistics*, the *Yearbook of Morphology*, and *English World-Wide*, as well as the editorial boards for three book series. He was the subject editor for Morphology in the first edition of the encyclopedia and is also a section editor for Morphology.

Natural Language Processing & Machine Translation – Graeme Hirst, *University of Toronto, Canada*

Graeme Hirst (Ph.D., Brown University, 1983) is a Professor of Computer Science at the University of Toronto, specializing in computational linguistics and natural language processing. Hirst's research has covered a broad but integrated range of topics in computational linguistics, natural language understanding, and related areas of

cognitive science. These include the resolution of ambiguity in language understanding; the preservation of author's style in machine translation; recovering from misunderstanding and non-understanding in human–computer communication; and linguistic constraints on knowledge-representation systems. His present research includes the problem of near-synonymy in lexical choice in language generation; computer assistance for collaborative writing; and applications of semantic distance in intelligent spelling checkers. From 1994 to 1997, Hirst was a member of the Waterloo-Toronto HealthDoc project, which aimed to build intelligent systems for the creation and customization of health-care documents. Hirst is a member of the editorial boards of *Machine Translation* and *Computational Linguistics,* and has been book review editor of the latter since 1985. He is the author of two monographs: *Anaphora in Natural Language Understanding* (Springer-Verlag, 1981) and *Semantic Interpretation and the Resolution of Ambiguity* (Cambridge University Press, 1987). He is the recipient of two awards for excellence in teaching. He has supervised post-graduate students in more than 35 theses and dissertations, four of which have been published as books. He is also a section editor for Natural Language Processing and Machine Translation.

Philosophy and Language – Robert J. Stainton, *University of Western Ontario, Canada*

Dr. Robert J. Stainton began his study of language and linguistics in the 1980s as an undergraduate at Toronto's York University, working under Prof. Michael Gregory in the systemic functional tradition. His doctoral training was at the Department of Linguistics and Philosophy at MIT, where he pursued course work in both domains and wrote a 1993 dissertation, *Non-Sentential Assertion*, that straddled the boundary between generative linguistics and philosophy of language. Stainton has authored or co-authored about 35 major journal articles and two books: *Philosophical Perspectives on Language* (Broadview, 1996) and *Knowledge and Mind* (MIT, 2000). His previous editorial work includes edited volumes from Blackwell, Broadview, Editions du GREF, Kluwer, University of Calgary Press, and Westview. He also currently serves as Philosophy of Language and Mind Editor for *The Canadian Journal of Philosophy.* At present, he is Canada Research Chair in Cognitive Science at Carleton University, in Ottawa, Canada.

Philosophy and Language – Alex Barber, *The Open University, UK*

Dr. Alex Barber has been interested in philosophical aspects of language and linguistics since his undergraduate studies. His doctoral thesis at McGill University dealt with some ramifications for philosophy of the shift toward cognitivism in linguistics, specifically the implications for received notions of knowledge in epistemology. His research has continued to focus on topics thrown up along the fault lines running between epistemology, philosophy of language, and philosophy of mind. He has contributed numerous articles in major philosophy journals and edited *Epistemology of Language* (Oxford, 2003). He has held teaching posts at the University of Bristol and the University of Sheffield, and is currently based in the Philosophy Department of The Open University.

Phonetics – John Esling, *University of Victoria, Canada*

John H. Esling is Professor of Linguistics at the University of Victoria, former Secretary of the International Phonetic Association (1995–2003), member of the IPA Council and of the Permanent Council for the Organization of ICPhS, and currently Editor of the *Journal of the International Phonetic Association*. He has a Ph.D. in phonetics from the University of Edinburgh, where he studied with David Abercrombie, John Laver, and James (Tony) Anthony, and he taught at the University of Leeds before moving to the University of Victoria in British Columbia, Canada, in 1981. His research is in auditory and articulatory phonetics, particularly the categorization of voice quality, vocal register, and the phonetic production of laryngeal and pharyngeal sounds.

He is director of the Phonetics Laboratory at the University of Victoria, the Laryngoscopic Phonetic Research Project, and the Infant Speech Acquisition Project, an international collaboration based in Victoria and funded by the Social Sciences and Humanities Research Council of Canada, with research teams

in Canada, France, Morocco, and China, to establish how infants first acquire the modality of phonetic production. He is the author of the *University of Victoria Phonetic Database* and an editor of the *Handbook of the IPA*.

Phonology – Richard Wiese, *University of Marburg, Germany*

Richard Wiese is a Professor of Linguistics in the Department of German Linguistics, Philipps-Universität Marburg, Germany. Before that, he held posts at a number of German universities, including those of Düsseldorf, Stuttgart, Kassel, Berlin, and Leipzig. His early work is on psycholinguistics (including his doctoral dissertation, *Psycholinguistische Aspekte der Sprachproduktion,* Buske 1983), while his more recent work focuses on theoretical phonology and morphology and on the description of German and Chinese (*Silbische und Lexikalische Phonologie. Studien zum Chinesischen und Deutschen,* Niemeyer, 1988; *Phonology of German,* OUP, 1996/2000; *Phonology and Morphology of the Germanic Languages,* Niemeyer, 1998, edited with Wolfgang Kehrein). He also conducts research on morphology and the mental lexicon and serves as co-editor of the book series *Linguistische Arbeiten* (Niemeyer).

Politics and Language – Ruth Wodak, *University of Lancaster, UK*

Ruth Wodak is Professor of Discourse Studies at Lancaster University since January 2004 (personal chair). She has just moved from Vienna, Austria, where she had been Full Professor of Applied Linguistics since 1991. She still commutes to Vienna to supervise her Ph.D. students there nearly every month. She has also stayed director of the Centre "Discourse-Politics-Identity," located at the University of Vienna (see http://www.univie.ac.at/discourse-politics-identity for research projects located there) and co-director of the Austrian National Focal Point (NFP) of the European Monitoring Centre for Racism, Xenophobia and Anti-Semitism (see http://www.eumc.eu.int for more information on the work of the EUMC and the NFPs).

Besides various other prizes, she was awarded the Wittgenstein Price for Elite Researchers in 1996, which made six years of continuous interdisciplinary team research possible. Her research is mainly centered on critical discourse analysis (CDA). Together with her colleagues and Ph.D. students in Vienna, she elaborated the "Discourse-Historical Approach in CDA," which is interdisciplinary and problem-oriented, and analyzes the change of discursive practices over time and in various genres. Her research agenda focuses on the development of theoretical approaches in discourse studies (combining ethnography, argumentation theory, and rhetoric and functional systemic linguistics); gender studies; language and/in politics; and prejudice and discrimination. Most recently, she started investigating debate forums in the Internet, such as http://www.europa.eu.int.

She is member of the editorial board of a range of linguistic journals, co-editor of the journal *Discourse and Society,* and editor of *Critical Discourse Studies* (together with Norman Fairclough, Phil Graham, and Jay Lemke) and of the *Journal of Language and Politics* (together with Paul Chilton). Together with Paul Chilton, UEA, Norwich, she edits the book series DAPSAC (Benjamins). She is also section editor of Language and Politics for the second edition of the *Encyclopedia of Language and Linguistics*.

She has held visiting professorships in Uppsala, Stanford University, University of Minnesota, and Georgetown University, Washington, D.C. In spring 2004, she was awarded a Leverhulme Visiting Professorship at the University of East Anglia, Norwich, UK.

Her current research projects include EMEDIATE (EU-funded project, STREP programme, starting in October 2004), XENOPHOB (EU-funded project), and "The Construction of European Identities – The Debates at the European Convention" (funded by the Austrian National Bank) (for more information on the research projects see http://www.univie.ac.at/ discourse-politics-identity/projects).

Pragmatics – Jacob L. Mey, *University of Southern Denmark, Denmark*

Jacob L. Mey is Professor Emeritus of Linguistics at the University of Southern Denmark. Previous appointments include the University of Oslo, Norway, the University of Texas at Austin, Georgetown University, Washington, D.C., Yale University, New Haven, Conn., Tsukuba University, Japan, Northwestern University, Evanston, Ill., City University of Hong Kong, Goethe University, Frankfurt am Main, Universidade Estadual de

Campinas, S.P., Brazil, Universidade de Brasília, Brasília, DF, the University of Haifa and Haifa Technion, Israel, as well as numerous other institutions of research and higher learning.

Mey's research interests concern all areas of pragmatics, with an emphasis on the social aspects of language use, the pragmatic impact of computer technologies, and the pragmatic use of literary devices. Among his publications in these areas are *Pragmalinguistics: Theory and Practice* (The Hague: Mouton, 1979); *Whose Language? A Study in Linguistic Pragmatics* (Amsterdam and Philadelphia: Benjamins 1985), *Pragmatics: An Introduction* (Oxford and Boston: Blackwell, 1993; second revised edition, 2001). This book has been translated into Japanese and Korean; a Chinese translation is about to appear (2002). His most recent publication is *As Vozes da Sociedade* (The Voices of Society; in Portuguese; Campinas, S.P.: Mercado de Letras 2002).

As to the computer-related aspects of pragmatics, a recent development is a new field, cognitive technology (CT), which he is among the first to have developed; he has written and edited numerous articles and books in the area, co-organized several international conferences, and founded (together with Barbara Gorayska) the *International Journal of Cognition and Technology* (Amsterdam: Benjamins; 2002). Among Mey's other main interests are the theory of literature and poetics. These interests have recently culminated (following many earlier articles) in his book: *When Voices Clash: A Study in Literary Pragmatics* (Berlin: Mouton de Gruyter, 2000).

Mey is Founder (with Hartmut Haberland) and Chief Editor of the monthly *Journal of Pragmatics* (Oxford: Elsevier Science). He also edits *RASK: International Journal of Languages and Linguistics* for Odense University Press, and co-edits (with Barbara Gorayska) the new *International Journal of Cognition and Technology* (Amsterdam and Philadelphia: Benjamins, from 2002). Among his other edited volumes are two readers on *Cognitive Technology* (1996, 1999), and the 1100-page *Concise Encyclopedia of Pragmatics* (1998), all published by Elsevier Science.

Mey holds an honorary Dr.Phil. degree from the University of Zaragoza, Spain. He is a member of various professional organizations, such as the Linguistic Society of America, the Copenhagen Linguistic Circle, and the International Pragmatics Association (of which he is a member of the Consultative Board). He is Editor or Member of the Advisory Board of a number of series and journals, such *as Pragmatics and Beyond* (Amsterdam), *Anthropological Linguistics* (Berlin), *Discourse and Society*; *Text*; *Language and Literature* (Liverpool); *Miscelánea* (Zaragoza); *Psyke og Logos* (Copenhagen); *Sémantique et Pragmatique* (Orléans), *Cadernos de Linguagem e Sociedade* (Brasília); and others. In 1998, he was elected to the office of Vice-President of the newly founded Society for Cognitive Technology.

Psycholinguistics – Anne Anderson, *University of Glasgow, Scotland*

Professor Anne H. Anderson, M.A. Ph.D. O.B.E, is a psycholinguist interested in communication, notably in dialogue and the impacts of new communication technologies on communication. Her research over several years has investigated how people communicate in dialogue and how communication systems do or do not replicate the advantages of face-to-face interactions. She has held many research grants on communication and the impacts of communication technologies and has published widely in the scientific literature with over 45 major scientific publications on human communication.

Professor Anderson was a principal investigator in the Human Communication Research Centre funded from 1990 to 2000 by ESRC. She has held a chair in psychology since 1997 at the University of Glasgow. The department was awarded the highest grade, a 5*, in the recent Research Assessment Exercise. From 1995 to 2000 she was director of the ESRC Cognitive Engineering programme, an initiative that funded projects across the UK on topics concerned with people and information technology. In 2000 she was appointed director of the People at the Centre of Information and Communication Technologies (PACCIT) programme, which is funded by ESRC, EPSRC, and the DTI and seeks to build research collaborations between universities and industry. She is also a section editor for Psycholinguistics.

Religion and Language – Erik Fudge, *University of Reading, UK*

Erik Fudge was Professor of Linguistics at the University of Hull, and is now Professor Emeritus of Linguistic Science at the University of Reading. After 30 years as a Lay Reader in the Church of England, he was ordained

priest in 1994. His first degree was in mathematics and modern and medieval languages at the University of Cambridge. After teaching in schools for 3 years, he took up research in linguistics at Cambridge, spending some time as Assistant Director of the Linguistics Research Project, Indiana University. He lectured in phonology at the University of Edinburgh (1965–19–68), and in phonetics and phonology at the University of Cambridge (1968–19–74), before taking up Chairs at Hull (1974–19–88) and Reading (1988–19–99). He was Editor of the *Journal of Linguistics* (1979–19–84), and was Section Editor for Phonology for the first edition of the Pergamon *Encyclopedia of Language and Linguistics*.

Semantics (Logical and Lexical) – Keith Allan, *Monash University, Australia*

Keith Allan, MLitt, Ph.D. (Edinburgh), FAHA, is Reader in Linguistics at Monash University. His research interests focus mainly on aspects of meaning in language, with a secondary interest in the history and philosophy of linguistics. Books include *Linguistic Meaning* (two volumes, Routledge and Kegan Paul, 1986), *Euphemism and Dysphemism: Language Used as Shield and Weapon* (with Kate Burridge, OUP, 1991), *Natural Language Semantics* (Blackwell, 2001). He is Semantics Editor for *International Encyclopaedia of Linguistics* (1994, second edition, 2003). His homepage with more information can be found at http://www.arts.monash.edu.au/ling/ka.html.

Semiotics – Marcel Danesi, *University of Toronto, Canada*

Marcel Danesi is Full Professor of Semiotics and Linguistic Anthropology at the University of Toronto. He is also cross-appointed as Professor of Communication Sciences at the University of Lugano. His research interests include semiotic theory, youth language, and mathematical puzzles. His most recent books in these three areas, respectively, are *Understanding Media Semiotics* (London: Arnold, 2003), *Forever Young: The "Teen-Aging" of Modern Culture* (Toronto: University of Toronto Press, 2003), and *The Puzzle Instinct: The Meaning of Puzzles in Human Life* (Bloomington: Indiana University Press, 2003). He is editor of the "Signs and Semaphores" book series with St. Martin's Press, and co-editor of the "Toronto Studies in Semiotics and Communications" Series with University of Toronto Press.

Sign Language – Bencie Woll, *University College London, UK*

Professor Bencie Woll came to the Department of Language and Communication Science at City University in 1995 to take up the newly created Chair in Sign Language and Deaf Studies, the first chair in this field in the UK. Professor Woll pioneered deaf studies as an academic discipline; her research and teaching interests embrace a wide range of topics related to sign language, including the linguistics of British Sign Language (BSL) and other sign languages, the history and sociolinguistics of BSL and the Deaf community, the development of BSL in young children, and sign language and the brain. She is the co-author of *The Linguistics of BSL: an Introduction* (CUP), the winner of the 1999 Deaf Nation Award and 2000 BAAL Book Prize.

Society and Language – Raj Mesthrie, *University of Cape Town, South Africa*

Rajend Mesthrie is Professor of Linguistics at the University of Cape Town. His work is on sociolinguistics generally, with a main focus on language contact and variation, with special reference to South Africa. He is currently the President of the Linguistics Society of Southern Africa. He has a long association with the Pergamon encyclopedia, having contributed seven articles to the first edition and having visited Ron Asher and Seamus Simpson in Edinburgh during its gestation. He edited the spinoff volume *Concise Encyclopedia of Sociolinguistics* (2001).

Among his recent publications are *Introducing Sociolinguistics*'(Edinburgh University Press, 2000, with J. Swann, A. Deumert, and W. Leap) and *Language in South Africa* (Cambridge University Press, 2002), of which he was editor.

Speech Technology – Jennifer Lai, *IBM Research, USA*

Jennifer Lai is a Senior Researcher in the Pervasive Computing Department at the IBM T.J. Watson Research Center in New York. Her expertise is in the design of human–computer interfaces, specializing in the use of speech recognition and synthesis technologies. Her research has covered a broad range of topics related to speech technologies and their integration into applications. These include the perception of synthetic speech; productivity applications for mobile workers; smart spaces; and multimodal interaction on pervasive computing platforms, as well as awareness servers; however, she is probably best known for her work defining design principles for effective conversational systems.

Lai has been a guest lecturer at MIT, Michigan University, and Pace University, and is a National Science Foundation panellist. She is a member of the Editorial Board for the *International Journal of Speech Technology*, the author of two book chapters, *Speech User Interface Evolution* (Kluwer, 1999), *Conversational Speech Interfaces* (LEA, 2002), and is widely published in the areas of speech interface design, perception of synthetic speech, and language model creation. She also holds seven patents related to interface design and has participated in numerous conferences as a program committee member, keynote speaker, session chairman, and panellist.

Spoken Discourse – Rosanna Sornicola, *Università di Napoli Federico II, Italy*

Rosanna Sornicola is Professor of General Linguistics at the Department of Modern Philology of the University of Naples Federico II, where she is also the Director of the European Master's Degree in Linguistics. She graduated in linguistics and modern philology at the University of Naples in 1975. She was Visiting Fellow at Wolfson College (Cambridge) in 1983 and 1987, Visiting Researcher at the Department of Linguistics of the University of California at Berkeley (1985), and Visiting Researcher at the Department of Italian of the University of California at Los Angeles (1988). She is a member of Wolfson College of the University of Cambridge. She was Visiting Professor at the Universities of California at Los Angeles (1990), Manchester (1990), Girona (1996), and Gand (1999), and has lectured in many other European Universities. She is a member of the scientific board of the reviews *Cahiers de linguistique romane*, *Lingue e Linguaggi*, *Revue de linguistique romane*, and is co-editor of the journal *Bollettino Linguistico Campano*. She has been a member of the Executive Committee of the International Society for Historical Linguistics and the Scientific Bureau of the Societé Internationale de linguistique et philologie romanes, and since 1999 has served as President of the Società di Linguistica Italiana.

Her research interests concern phonetic, phonology, syntax and pragmatics of spoken language, the relationship between spoken and written discourse, Italian and Romance sociolinguistics and dialectology, synchronic and diachronic typology, and history of linguistics (especially the history of European functionalism). Her publications include the following books: *La competenza multipla* (Napoli, Liguori, 1977), *Sul parlato* (Bologna, Il Mulino, 1981), *Il campo di tensione. La sintassi della Scuola di Praga* (co-editor with Aleš Svoboda, Napoli, Liguori, 1992), *The Virtues of Language. History in Language, Text and Literature* (co-editor with Dieter Stein, Amsterdam, Benjamins, 1998), *Stability, Variation and Change of Word Order Patterns over Time* (editor with Erich Poppe and Ariel Shisha Ha-Levy, Amsterdam, Benjamins, 2000), *Langue écrite, langue parlée dans le passé et dans le present* (co-editor with Rika van Deyck and Johannes Kabatek, Tübingen, Narr, forthcoming). She is also author of many articles published in books and journals.

Syntax – James P. Blevins, *University of Cambridge, UK*

James Blevins received his Ph.D. in linguistics from the University of Massachusetts, Amherst in 1990. After working on natural language processing at the Microelectronics and Computer Technology Corporation in Austin, he taught in the Linguistics Programme and coordinated the Cognitive Science Programme at the University of Western Australia, before moving to the Research Centre for English and Applied Linguistics in the University of Cambridge.

He has held visiting positions at the Universities of California, Texas, and Alberta, and is on the editorial board of *Languages in Contrast*. His main research interests fall within the domain of syntax and morphosyntax.

Recent publications in the area of syntax and syntactic theory include 'Markedness and agreement' (*Transactions of the Philological Society*, 98, 2000), 'Nontransformational grammar' (*The Linguistics Encyclopedia*, K. Malmkjaer, ed., Routledge, 2002), 'Passives and impersonals' (*Journal of Linguistics* 39, 2003), 'Feature-based grammar' (*Non-transformational syntax*, R. D. Borsley and K. Borjars, eds., Blackwell, 2003), and 'Remarks on gerunds' (*Morphology and the Web of GRAMMAR: Essays in memory of Steven G. Lapointe*, O. Orgun and P. Sells, eds., CSLI, 2003).

Text Analysis and Stylistics – Catherine Emmott, *University of Glasgow, Scotland*

Catherine Emmott is a Senior Lecturer in the Department of English Language at the University of Glasgow, Scotland. She is author of the book *Narrative Comprehension: A Discourse Perspective*, as well as articles on written text analysis, stylistics, narratology and discourse anaphora. She is Assistant Editor of the journal *Language and Literature* and Director of the Glasgow LINCS Project ("Literature, Narrative and Cognitive Science: Interdisciplinary Perspectives on the Nature of Reading").

Translation – Kirsten Malmkjær, *Middlesex University, UK*

Kirsten Malmkjær is Professor of Translation Studies and Literary Translation and Head of Middlesex University Translation Institute. She studied English and philosophy at Birmingham University, where she also taught for four years before moving to the University of Cambridge, Research Centre for English and Applied Linguistics. She led the Centre's M.Phil. in English and Applied Linguistics until April 1999, when she took up her Chair at Middlesex to concentrate on her main research and teaching interest in translation studies. She publishes widely in translation studies and is co-editor of the journal *Target* (John Benjamins).

Typology and Universals – Bernd Heine, *University of Cologne, Germany*

Bernd Heine is Professor of African Languages and Linguistics at the University of Cologne, Germany. He has held visiting professorships at the University of Nairobi, La Trobe University (Melbourne), University of New Mexico (Albuquerque), and Dartmouth College (New Hampshire), was a visiting scholar at the Center for Advanced Study (Stanford) and the Institute for Advanced Study (Melbourne), and has carried out over 20 field research trips to Africa. He is member of the North Rhine-Westphalian Academy of Science and is a corresponding fellow of the British Academy. He has published 32 books and over 100 papers on African linguistics, language typology, and grammaticalization theory. His latest books are *Cognitive Foundations of Grammar* (Oxford University Press, 1997), *Possession* (Cambridge University Press, 1997), and *World Lexicon of Grammaticalization* (Cambridge University Press, 2002, co-edited with Tania Kuteva).

Variation and Language – Miriam Meyerhoff, *University of Edinburgh, Scotland*

Miriam Meyerhoff teaches sociolinguistics at the University of Edinburgh, Scotland. She is interested in different aspects of language variation and change and has conducted research on structural change in creole languages in the Pacific (Vanuatu and Hawai'i) and the Caribbean (Bequia). She has also worked on changes taking place in New Zealand English, and has investigated the role variation plays in understanding the social construction of gender. She is the author of *Constraints on Null Subjects in Bislama (Vanuatu)* (2000) and co-editor of *The Handbook of Language and Gender* (2003).

Writing Systems – Peter T. Daniels, *Independent Scholar, USA*

Peter T. Daniels is one of the world's few scholars specializing exclusively in the study of writing systems. With degrees in linguistics from Cornell University and the University of Chicago, he has taught at the University of Wisconsin–Milwaukee and Chicago State University and has presented invited lectures on three continents. His

translations include *Introduction to the Semitic Languages*, by Gotthelf Bergsträsser, and *From Cyrus to Alexander: A History of the Persian Empire*, by Pierre Briant (both published by Eisenbrauns). He is author of numerous articles and reviews on writing and on the topic of languages of the world; co-editor and principal contributor to *The World's Writing Systems* (Oxford, 1996); and consulting editor for issues of the children's magazines *Calliope* and *AppleSeeds* devoted to writing, to appear in 2004. He lives in New York City.

NOTES ON THE SUBJECT INDEX

The following abbreviations have been used:

F0 – fundamental frequency

IPA – International Phonetics Alphabet

L2 – second language

PIE – Proto Indo-European language

NOTES ON THE GLOSSARY

The glossary is based on the glossary from the first edition of the *Encyclopedia of Language and Linguistics*. It has been revised throughout, and has benefited greatly from input from a number of the Section Editors and other contributors to the encyclopedia.

Small capitals refer to fields or subfields in the main encyclopedia. Terms in bold type refer to other entries within the glossary.

NOTES ON THE LIST OF LANGUAGES

Data in this list are reproduced with permission from the 15th edition (2004) of *Ethnologue: Languages of the World* (Dallas: SIL International), edited by Raymond G. Gordon Jr.

Please note: All the data in this list of languages are reproduced from Ethnologue data. In some cases there may be differences between this data and the information presented in articles: in particular, the names and alternative names of languages and dialects; the identification and classification of dialects; the estimates of the number of speakers of a particular language or dialect. These discrepancies are due to the uncertain state of knowledge about many of these matters and to conflicts between information sources themselves. Readers who find gross discrepancies should check both the Ethnologue references and the references in the various articles in the Encyclopedia.

The entries are set out in three lines:

Line 1: the name of the language (in bold); followed by the three letter ISO language identifier enclosed by square brackets, followed by alternative names for the language, if there are any.
Line 2: the genetic affiliation of the language.
Line 3: the total number of speakers; followed by the countries where the language is spoken and the number of speakers in each country.

Thus:

Abaza [abq]: Abazin, Abazintsy, Ahuwa, Ashuwa, Tapanta.
North Caucasian, West Caucasian, Abkhaz-Abazin.
44,895: Russia 34,800; Turkey 10,000.

Abkhaz [abk]: Abxazo.
North Caucasian, West Caucasian, Abkhaz-Abazin.
105,952: Georgia 101,000; Turkey 4,000 [ethnic population: 39,000].

The list contains 7,299 **language names** as head words. There are three or four times that many alternative language names: those listed are derived from Ethnologue and may or may not correspond to alternative language names used in the various articles in the encyclopedia. The identification of a "tongue" as a distinct language is a well-known difficulty, and naming languages is another. The Ethnologue approach to these issues is explored in the article "Ethnologue" in the encyclopedia. In ELL2 we have decided to standardize on Ethnologue names to achieve consistency across the encyclopedia since there is no other source of information about languages that is as comprehensive. In the list of languages, Ethnologue names are used as headwords. However, in articles on particular languages and in the articles in the Countries and Languages section languages appear under the name preferred by the author, which may or may not be the Ethnologue name. Typically where this name differs from the Ethnologue name there is a "dummy entry" under the Ethnologue name cross-referring to the entry under the non-Ethnologue name.

The **ISO language identifier** codes are three-letter language identifiers that aim to provide identifiers for all known languages. They were first adopted as an American National Standard in 1987 and have been subject to revision since then. The codes used here are the most up-to-date. They are used in Ethnologue and are the Draft International Standard codes of ISO/DIS 639–3. The article "Ethnologue" contains further details.

The **genetic affiliation** shows the language family under which it is currently classified in Ethnologue from the most comprehensive, top-level grouping (North Caucasian in the examples above) down to the smallest (Abkhaz-Abazin in the examples). The genetic classifications identify 94 different top-level language families and in some cases have six or seven levels of grouping. It should be noted that the classification used in the articles in this encyclopedia, explained in the article "The Classification of Languages," is compatible with that used by Ethnologue, but is less fine grained.

It is not possible to give precise figures about the **number of speakers** of particular languages since the

data sources are not always reliable and may differ from each other. The speaker numbers in the list of languages are taken from Ethnologue, which also provides summaries of speakers in particular countries, the distribution of populations within language families, etc. Speaker numbers given in articles in the encyclopedia sometimes differ from those given in this list, depending on the source of the data. The annotation "Ethnic population" in the Abkhaz entry relates to the fact that whereas the estimated ethnic population of Abkazians is 39,000, the number of speakers is 106,000.

A list of articles in the encyclopedia dealing with individual languages can be found in the subject classification, as can a list of countries discussed in individual articles.

LANGUAGE MAPS

Appendix I: Language Maps

These language maps are reproduced with permission from the 15th Edition of *Ethnologue: Languages of the World* (Dallas: SIL International), edited by Raymond G. Gordon Jr.

There is a map associated with every article in the 'Countries and Languages' section – that is, with every article with a title in the format of 'Country name: Language Situation.' Every article in the 'Languages of the World' section is cross-referenced to the corresponding language situation article, and hence to the relevant language map. Thus, every language discussed in this encyclopedia is associated with a map.

A

A Priori Knowledge: Linguistic Aspects

G Lavers, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Immanuel Kant made two divisions between types of knowledge. He distinguished between the *a priori* and the *a posteriori* and also between analytic and synthetic judgments. *A posteriori* claims are the most simple to categorize: They include all empirical knowledge. Everything we learn about the world through our senses falls under this category. *A priori* knowledge is knowledge the ultimate justification of which is independent of experience. However, to call a piece of knowledge *a priori* is not to claim that the knowledge is literally prior to all experience (innate). For instance, mathematical knowledge is widely taken to be *a priori*. That is not to say that no experience is necessary to learn mathematical truths. When one claims that mathematics is *a priori,* this means that experience plays no role in the *justification* of a mathematical proposition. The justification and what led one to believe a proposition (the cause of the belief) need to be carefully distinguished. One may require paper and pencil to convince oneself that a certain mathematical proposition is provable. However, once proven, it is the proof and not the experience of the written proof that is the ultimate justification for the proposition.

A proposition is analytic according to Kant if it is true by virtue of meaning. For instance, the claim that all bachelors are unmarried is an analytic proposition because 'bachelor' just means unmarried man. For Kant and most of the analytic tradition in philosophy, all analytic truths are *a priori*. Because analytic claims are true in virtue of meaning, their justification is nonempirical.

Kant was of course familiar only with Aristotelian logic in which the only logical relation is that of containment between subject and predicate. He therefore equated the property of being true by virtue of meaning with being a logical truth in this sense. In the example above, for instance, it is true because the class of unmarried things includes the class of bachelors. A proposition is analytic according to Kant therefore if and only if the subject concept is contained in the predicate concept.

Whereas all analytic claims are trivial, a synthetic claim is any claim that genuinely extends knowledge. All empirical claims are of this sort, but Kant argued that there were also nontrivial *a priori* truths. Kant held that the class of synthetic *a priori* truths included both geometry and mathematics. Mathematics is synthetic because, for instance, 12 is nowhere contained in the concepts of 7, addition, and 5. Mathematics is also *a priori* because it does not depend for its justification on experience. To show that (Euclidean) geometry must be *a priori,* Kant provided an argument that he called the 'transcendental esthetic.' Here Kant argued that geometrical relations cannot be learned through experience, because to understand something as located in space, we must have already organized our sensations spatially. That is to say, if our minds did not organize sensations spatially, we could not learn anything concerning the structure of space though sensation. This faculty of ours to organize sensations into a single Euclidean space Kant called our form of spatial intuition. That it is our minds that organize experience into a three-dimensional Euclidean space allows Kant to claim that even though geometrical claims are synthetic, they are nonetheless *a priori*. The structure of space is not learned from experience; it is known through the pure intuition of space. Our pure intuition of space is what allows us to have nontrivial *a priori* knowledge in geometry. Kant also argued that we must have a pure intuition of time because if we did not organize our sensations temporally we could not learn of temporal relations through sensation. It is this pure temporal intuition that Kant believed allows us to have synthetic *a priori* knowledge in mathematics.

Kant thought he had established that the laws of Euclidean geometry were synthetic *a priori* truths about empirical space. Yet, even as Kant was writing the arguments just presented, work was being done on the development of non-Euclidean geometries. Later, Hermann von Helmholtz showed that it is possible to imagine a set of experiences that would

lead one to believe that space is non-Euclidean. By the end of the 19th century, the geometry of our space was considered an open question. In Bertrand Russell's fellowship thesis, he argued that which geometry applies to our space is an empirical question.

Henri Poincaré took issue with Russell's assertion that the geometry of our space is a straightforwardly empirical question. If, for instance, we construct a large triangle out of light rays and then measure the angles and find that they do not sum to 180 degrees, we cannot yet say that the geometry of space is non-Euclidean. This is because, as Poincaré stressed, we require the further assumption that light travels in a straight line. Poincaré argued that, to preserve the simplicity of Euclidean geometry, we are free to postulate that the path of the light rays is not a straight line. He believed that we are free to hold either that light travels in a straight line and space is non-Euclidean or that space is Euclidean and light does not travel in a straight line. Given this situation, it is incorrect to say that space has a certain geometry. The question of the geometry of space is as meaningful as the question of whether space ought to be measured in inches or centimeters. The various geometries are purely abstract theories that say nothing about empirical space until certain stipulations have been made concerning the types of things that are to count as straight lines.

In 1915, Albert Einstein produced his general theory of relativity. This theory, which asserts that the curvature of space depends on the distribution of matter, is well confirmed. Furthermore, there is no flat space-time theory that makes the same predictions as general relativity. Given this situation, we are no longer free, as Poincaré assumed, to retain Euclidean geometry, come what may. However, Poincaré's point that, without intervening assumptions, geometrical propositions say nothing about empirical space still holds. We need to specify that the straight lines through space-time are the paths of freely falling bodies. It now seems clear that what Kant took to be synthetic *a priori* truths about empirical space are actually false. Hence, Einstein's famous quote: "As far as the laws of mathematics refer to reality, they are not certain; and so far as they are certain, they do not refer to reality."

The reaction in the philosophical community – especially the logical positivists in the early 20th century – to the situation just described was to reject the synthetic *a priori*. All *a priori* truths were taken to be analytic. This was motivated not only by the considerations above but also by the development of modern logic that expanded the class of logical truths significantly. Such a statement as 'if there is someone who knows everyone, then every one is known by at least one person' can now be shown to be a logical truth, but it is certainly not a case of the subject being included in the predicate. Thus, the category of analytic *a priori* truths is expanded, and the class of synthetic *a priori* truths is eliminated entirely. The logical positivists also relativized the *a priori*. Any statement that we wish to hold as a matter of stipulation gains the status of an *a priori* truth. Definitions of theoretical terms or relations between theoretical terms can be taken to be *a priori*. If the theory that they are part of is modified or abandoned, they are no longer taken to be *a priori*. So, the class of *a priori* propositions is revised as we revise our theories.

According to the positivists, the model of scientific theories is as follows. Scientific theories are composed of a certain class of purely theoretical sentences that are taken to be analytic and *a priori*. Given that these claims are purely theoretical, they make no assertions about things that can actually be observed. This independence from anything observable explains their *a priori* status. These sentences are seen as true in virtue of meaning. However, there will also be a class of sentences that relate this theoretical vocabulary to things that can be observed. These are called 'correspondence rules.' These correspondence rules serve to give an empirical interpretation to the theoretical vocabulary.

This positivistic theory of theories came under heavy attack by W. V. O. Quine in the middle of the 20th century. In particular, Quine attacked the division of sentences into analytic and synthetic. For the positivists, given their rejection of the synthetic *a priori*, the rejection of the analytic/synthetic distinction amounts to a rejection of the *a priori/a posteriori* distinction as well. Quine thought that the difference between analytic and synthetic sentences is a matter of degree, rather than a difference in kind. His view was based on two observations. First, the distinction between observational and theoretical vocabulary is itself a difference of degree. Second, because we can reject highly theoretical sentences on the basis of making certain observations (if the theory as a whole is rejected), then it does not seem reasonable to claim that these sentences are independent of experience. For the positivists, such sentences as 'force equals mass times acceleration' function as a definition of force in Newtonian physics and are thus true in virtue of meaning, and hence, *a priori*. Yet, this claim, according to the positivists, says nothing about the world.

Quine stressed that individual sentences do not have identifiable content, but rather, it is theories as wholes that make assertions about the world. Thus, the definition of force, as part of Newtonian physics, does make an assertion about the world

(in this case, that the world is Newtonian). Quine's view that there are no analytic or *a priori* sentences was widely influential; however, there is now renewed interest in making the distinction between *a priori* and *a posteriori* assertions to better understand how scientific theories function.

Quine's attack on the analytic/synthetic distinction eventually faced empirical scrutiny. Linguists such as Noam Chomsky and Ray Jackendoff have shown that there are empirical reasons to hold that there is an analytic/synthetic distinction. Certain sentences seem to show analytic connections with one another. For instance, upon hearing the sentence 'Jane was convinced to leave' one will assume that Jane decided to leave. An analytic sentence is one whose truth is given by the existence of such a connection. Analytic sentences in this sense are true in virtue of meaning. They are also knowable independent of experience and thus *a priori*. However, that they are knowable independently of experience is not itself knowable *a priori* but known though empirical investigation of natural language. Kant imagined that we could identify *a priori* truths *a priori*. Here we have a case of *a priori* truths that are dicovered empirically. On this view *a priori* truths can have no foundational epistemological status.

It had been almost universally believed that all analytic claims were *a priori*. This position is shared by Kant and the positivists (the positivists went further in claiming that all *a priori* claims were analytic). However, on the basis of work by Saul Kripke and Hilary Putnam, a case can be made that certain claims are both analytic and *a posteriori*. That is, there are claims that are true in virtue of meaning, but are not knowable independently of experience. For instance, part of the meaning of the term 'water' is that it is composed of H_2O. So the sentence 'water is H_2O' is true in virtue of meaning, and thus analytic. However, this sentence is nonetheless a substantial claim about the world and certainly not knowable independently of experience, and thus it is *a posteriori*.

Aalto, Pentti (1917–1998)

A Parpola, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Pentti Aalto, born in 1917 in Pori (Finland), took his M.A. in Latin, Greek, Sanskrit, and Altaistics at the University of Helsinki in May, 1939. During World War II, he served in the Finnish Army as an officer charged with decoding enemy ciphers. After the war, he continued his studies, partly in Sweden, and defended his doctoral thesis in Helsinki in 1949. Aalto was Docent of Comparative Linguistics from 1949 to 1958 and Professor of Comparative Linguistics from 1958 to 1980 at the University of Helsinki.

His first major publications dealt with the history of Latin gerund and gerundive (1949) and Greek infinitive (1953). After the death of his teacher G. J. Ramstedt in 1950, Aalto edited Ramstedt's main work, a comparative grammar of the Altaic languages (1952–1966), and many of his unpublished papers. Aalto's own critical edition of the Mongolian version of the Buddhist text *Pañcarakṣā*, translated from Tibetan, appeared in 1961. Together with his student, the Latinist Tuomo Pekkanen, Aalto published an important collection (1975–1980) of Latin sources on the peoples of Northeast Asia, spanning from antiquity to the times of Charles the Great. Aalto wrote (1971–1987) the history of Oriental, classical, and modern language studies in Finland during the period of the Russian rule. A selection of the hundreds of articles and reviews written by Aalto was published in 1987.

A-Morphous Morphology

S R Anderson, Yale University, New Haven, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

A-Morphous Morphology (Anderson, 1992) is a framework for the analysis of complex words (including inflection, derivation, compounding, and other types of word formation). It is a realizational framework in the sense that it sees morphology as establishing a many-to-many correspondence between aspects of a word's form and aspects of its content rather than as concatenating a series of purely local sound-meaning correspondences (morphemes). It is a lexicalist and postsyntactic view in that it maintains that the content and internal form of words are neither accessible to nor manipulated by principles of the syntax. The only interface between words and the syntax is an informationally minimal morphosyntactic representation, comparable in most respects to the complex symbols of Chomsky (1965).

The most distinctive aspect of this point of view is its rejection of the classical morpheme, traditionally the cornerstone of morphological analysis. Word structure is built up through modifications to a basic stem, including affixation as one among several formal possibilities. Once an affix is associated with a stem, however, the result is not presumed to have internal structure of a nonphonological sort. Some complex words (particularly compounds) generally **do** have such a structure, but the mere fact that a word's form is motivated in part by relations to other words does not in itself establish that.

Reasons to Reject the Classical Morpheme

The starting point of morphological analysis is what de Saussure referred to as the partially motivated sign, in which the relation between the form of a word and its (complex, analyzable) content can be decomposed into parts, some of which it shares with other words. Content here refers both to the lexical meaning of the word and to the morphosyntactic categories that influence its form. In sets of morphologically complex words, similarities of form correlate with similarities of meaning. For structuralist theory, these similarities inhere in structural units, morphemes, which have the character of Saussurean minimal signs. A morpheme is a "linguistic form which bears no partial phonetic-semantic resemblance to any other form" (Bloomfield, 1933: 161), or a "minimal same of form and meaning."

On that view, words are taken to be exhaustively analyzable into a sequence of such minimal signs or morphemes. Because the basis of the sign is the indissoluble unity of sound and meaning (and [morpho]-syntax), there should then be a one-to-one association between elements of form and elements of content. That is, every chunk of form ought to correspond to exactly one chunk of meaning, and vice versa. Only in unsystematic instances of accidental homophony or synonymy should we find exceptions to this.

In fact, however, the notion that the elemental building blocks of words can be discovered by looking for recurrent relations between form and meaning is falsified in both directions. One problem is the existence of phonæsthemes. In sets of words such as *glimmer, glitter, gleam, glow*, . . . ; *slide, slip, slither, slink, slippery*, . . . we find a shared aspect of meaning and a similarity of form, but (whatever the etymological source of such relations) speaker intuitions reject the notion that *glimmer*, for example, is composed of two elements, *gl-* and *-immer*, in the way *bookish* is composed of *book* and *-ish*. It will not do to say that only one of the parts here (presumably *gl-*) has a separable meaning because the same could be said for words such as *raspberry*, in which only the *-berry* part has a meaning apart from the combination but speakers do not hesitate to see the word as internally complex.

The other side of this coin is the existence of word-internal structure in which neither formal component of a complex word can be regarded as having distinct content. This is the case with sets of English verbs composed of a prefix and a stem (e.g., *deceive, receive, defer, refer*), neither of which makes a consistent contribution to the content of combinations including them (Aronoff, 1976).

Even ignoring such problems that arise when we attempt a parallel division of the form and content of

words, other difficulties appear within the domain of form itself. Consider a word such as English *amorphous* 'having no definite form', for which we can represent the relation between form and content roughly as follows (where a μ represents a morpheme, and an X represents a segmental position in phonological structure):

(1)

The classical hypothesis that words can be exhaustively decomposed into a linear concatenation of morphemes can be regarded as making several distinct claims about structures such as that in (1):

1. Each part of the content is linked to exactly one μ.
2. Every X is linked to exactly one μ.
3. Every μ is linked to at least one X and to some part of the content.
4. Lines do not cross.

Problems in the Relation between Form and Content

As has been well known at least since the discussion in Hockett (1947), these claims are falsified in the general case by phenomena that are quite uncontroversial. For instance, circumfixes (e.g., Indonesian *kebisaan* 'capability') present morphological units that are not continuous and for which the linking lines in a representation such as (1) would have to cross, violating claim 4. The same is true for infixes, for example, Sunda (Sundanese) *ɲaraian* 'to wet (pl.)', whose presence in a word renders the stem discontinuous.

Problems of a slightly different sort arise when some aspect of content is connected not with an entire segment (or sequence of segments) but only with a subset of the features of a segment (e.g., Irish Gaelic *asal* [asəl] 'donkey', *asail* [asəl'] 'donkey.GEN'; *bád* [ba:d] 'boat', *báid* [ba:d'] 'boats'). Here the required modification of the picture in (1) is straightforward, however, given modern notions of phonological structure.

A somewhat different problem is presented by the existence of empty morphs, or structural units with no content (thus violating claim 3), such as the underlined portions in English *crime/criminal*, *page/paginate*; or *sense/sensuous, habit/habitual/habituate*. Similar elements are found in Spanish *madre/madrecita* 'mother'/'mother DIM' (cf. *comadre/comadrita* 'god mother'/'god mother DIM') and Russian *slog* 'syllable', *slogovoj* 'syllabic' (cf. *odno-složnyj* 'monosyllabic'). In Menomini *ketōs* 'my canoe' the initial *ke* represents 'my' and *os* is 'canoe'; the *t* that separates them is a meaningless element that appears in possessive constructions with vowel-initial stems.

In some ways even more problematic is the case of superfluous morphs. In words such as *lengthen, strengthen*, or French *doucement* 'softly', the underlined element is one to which we can assign a sense (in English *-th* forms nouns from adjectives, and in French the medial schwa and associated consonant is the mark of the feminine), but that sense is inappropriate to these forms. *Strengthen* does not mean 'to make strength' but 'to make strong', and there is no role for the feminine agreement in the adverb *doucement*.

Just as words may contain elements of form with no (appropriate) content, there may be elements of content that correspond to no unit of form, again violating claim 3. In *The deer are running away*, we say that *deer* is a plural, but there is no overt representation of that. This is typically described by positing a zero morph to represent the plural here, analyzing the word's content as *deer* + PL and its form as /dir+0/. In general, however, there is no evidence for a structural element in such cases apart from the need to preserve parallelism between the analyses of meaning and form. The notion of a zero morph, then, is not a solution to this difficulty but merely a name for it.

The notion that components of meaning are related in a one-to-one fashion to elements of form (claims 1 and 2) is similarly falsified in both directions. Instances of cumulative morphs or multiple exponence (e.g., Chickasaw *hilhali* 'I'm dancing' vs. *akhi'lho* 'I'm not dancing', in which four distinct components of the second form all correspond to the single content element NEGATIVE) show that several quite distinct parts of a form can all be part of the realization of a single component of its meaning; whereas portmanteaux such as French *au* [o] (= *à le*) show that a single unitary and indecomposable element of form can correspond to more than one structurally significant aspect of its content.

In general, the relation between components of form and components of the meaning of a word is many-to-many rather than one-to-one and, in mathematical terms, not onto in either direction. The

many-to-many nature of this relation is illustrated in the analysis of the Icelandic verb *hafðir* 'you (sg.) had' in (2), where the relations between phonological form and components of content are indicated by lines.

(2)

Problems in the Analysis of Morphological Form

In the traditional morpheme-based view of word structure, the relation between a base and a (complex) word derived from it consists exactly in the addition of one or more minimal sound-meaning complexes. As a result, sign composition within such a theory must always be strictly monotonic (additive, concatenative), on the model of (3), in terms both of sound and of meaning.

(3)

A *prima facie* problem for such a principle is the existence of numerous sorts of apophony (including umlaut, ablaut, and gradation), as illustrated in English sets such as *sing, sang, sung, song*; *dive, dove*; *(wo)man, (wo)men*; *sell/sale*; *blood/bleed, food/feed* and *believe/belief, prove/proof, speak/speech*; *bath/bathe, breath/breathe, glass/glaze* (provide with glass), *refuse* (noun)/*refuse* (verb). In all these types, some additional morphological content is signaled not by the addition of formal material to the base but rather by a (nonmonotonic) change in some vowel or consonant of the base. There is no natural way to treat the added element of meaning in the derived forms as the result of an additional morpheme of the classical sort.

Exchange rules (e.g., Diegueño (Kumiái) *ɬʸap* 'burn (sg.)' vs. *ɬʸa:p* 'burn (pl.)', *sa:w* 'eat (sg.)' vs. *saw* 'eat (pl.)', where plurality is marked by lengthening a short vowel or by shortening a long vowel in the base) represent a kind of apophonic relation that is particularly difficult to analyze in terms of morphemes. Whatever might be treated as the marker of the category in question (vowel lengthening as a marker of plurality, in the Diegueño example) in some instances is precisely what must be **undone** in the others. No single formal element can serve both purposes.

A similar (if not even more acute) problem is presented by instances in which a derived morphological category is built through a formal operation of subtraction, as in Icelandic *hamr* 'hammering' from *hamra* 'to hammer'; Huichol *nepizeiya* 'I saw him IMPERF' *nepizei* 'I saw him PERF'; *pïtiuneika* 'he was dancing', *pïtiunei* 'he was dancing PERF'.

Metathesis of segments as a way to encode morphological information (e.g., Clallam *čkʷú-t* 'shoot' vs. *čúkʷ-t* 'shooting', where the second or nonactual form is derived from a basic actual form by inverting the order of a vowel and a consonant) is also inconsistent with the classical notion of the morpheme. In such cases, no new formal material is added; rather, the material in the base is reorganized as a way of marking a morphological category.

Morphological types of the sort just surveyed, in which the possibility of a concatenated formal marker of a morphological category is apparently problematic, have been widely discussed in the literature. What is less often remarked is that similar problems arise on the content side. Morphology, that is, may be semantically as well as formally nonconcatenative. An example is provided by the category of Icelandic middle voice verbs derived by the addition of the ending *-st*. Compare *gleðja* 'gladden (TRANS)', *gleðjast* 'rejoice'; *lýja* 'tire (someone) out', *lýjast* 'get tired, worn out'; *opna* 'open (TRANS)', *opnast* 'open (INTRANS)'; *heyra* 'hear', *heyrast* 'be audible'; and *týna* 'lose', *týnast* 'be, get lost'. In each case, the semantics of the base verb can be represented roughly as in (4).

(4) (CAUSE x, (BECOME (P y))) (e.g., 'SUBJ causes OBJ to become joyous, tired, open, etc.')

The effect of adding the ending *-st* is to delete the highest predicate (CAUSE x,y) from this structure while also deleting the corresponding argument position and/or θ-role from the syntax. Formally additive morphology, that is, is accompanied by subtractive semantics – again, a situation that is quite incompatible with the notion that morphological information is carried exclusively by a set of minimal sound-meaning pairs, or morphemes.

The conclusion must be that morphology involves relations between forms, not simply the concatenation of primitive units of sound and meaning. These relations in the general case can be represented

as realizational processes (Word Formation Rules, functions from words to other words). This is more general than the affixation view because although affixation can always be expressed as a process ('Add *-able*'), not all processes can be coherently expressed as affixes.

The Relation between Morphology and Syntax

Apart from its rejection of the traditional morpheme as the basis of morphological structure, A-Morphous Morphology is distinguished from other views of word structure in terms of the way it views the interaction of morphology and syntax. Although these matters are logically separable from the issues of the preceding section, they cohere with the realizational picture of word formation in the assumptions made about the nature of linguistically significant representations.

Implications of Lexicalism for Morphology

Work within the framework of A-Morphous Morphology is based on a particular interpretation of the Lexicalist Hypothesis: the syntax neither manipulates nor has access to the internal form of words. Taken in its strictest sense, this implies that nothing in the syntax can affect the forms of words or be based on the morphological information they contain. Such a position is clearly too restrictive because a number of types of morphology clearly interact with the syntax. These can be grouped into four overall types.

Configurational properties are assigned on the basis of the larger syntactic structure within which a word appears. For instance, in English, the genitive is assigned to nominals in the determiner position within another nominal, as in [$_{DP}$ [$_{det}$ [$_{DP\ [+gen]}$ John's]] hat].

Agreement properties are assigned to words by reference to the value on the same dimension of some other item within the same syntactic structure *The cat sleeps on the bed* vs. *The dogs sleep on the floor.*

Phrasal properties are assigned to larger constituents within a structure (typically, maximal projections – full phrases), but they may be realized on individual words that constitute only part of those structures, such as the genitive in *the king of England's crown*.

Inherent properties are lexical characteristics of individual words such as gender or word class that must be accessible to syntactic principles of agreement and the like.

These properties are all, of course, subtypes of what is traditionally called inflection. This suggests the hypothesis that inflection is exactly the morphology that is accessible to and/or manipulated by rules of the syntax. Because all traditional attempts to define inflection seem to fail (Anderson, 1992), such a theory-internal definition seems the only way to give substance to this standard subdivision of morphology.

Other ways of resolving the apparent conflict between the Lexicalist Hypothesis and the demands of inflectional morphology exist, but they have problems of their own. It might be, for example, that the Lexicalist Hypothesis is simply wrong and should be rejected. Eliminating it altogether, however, potentially opens the floodgates for many kinds of interaction between morphology and syntax that are not actually observed. The four property types just noted seem to exhaust the cases in which syntax and morphology must be allowed to affect one another.

Alternatively, we might propose that inflectional marking of the types identified in the Lexicalist Hypothesis is not actually done in the syntax; rather, the formal marking all takes place in the lexicon and the morphological marking of individual words is then checked elsewhere (in the syntax, in some Minimalist work; or in the semantics). This checking is not as simple as it may appear, however, and a thoroughgoing application of this approach in morphologically complex languages forces the description to redundantly duplicate morphological structure in two parts of the grammar: On the one hand the form must be properly constructed in the lexicon, while on the other the surface result must be deconstructed according to the same generalizations in the syntax so as to ensure that it is correct. It seems better to assume that the theory of inflection is exactly a theory of the ways in which the scope of the strong form of the Lexicalist Hypothesis must be refined and circumscribed.

The Interface between Syntax and Morphology

In order for words to be inflected in ways appropriate to the syntactic positions in which they appear, there must clearly be some interchange of information between syntactic and morphological principles. As discussed in the previous subsection, this is precisely the way in which the scope of the Lexicalist Hypothesis must be restricted. But this leads us to ask what form the interface between the two domains of grammar should take.

The classical view is that the information shared between syntax and morphology about a word is a (structured) division of the word into its constituent morphemes, with a gloss for each, such as the analysis of the Georgian verbal form in (5).

(5) mo-g-k'lav-s
PVB-2.OBJ-kill-3.SUBJ
'he will kill you'

(where PVB stands for preverb). When considered in detail, however, there are a number of problems for this apparently commonsense view.

One large class of problems is directly related to the issues raised previously. Morphologically relevant information about a word is often carried by nonaffixal morphology, such as apophony (ablaut, umlaut, etc.), consonantal mutations, subtraction, and the like. Whenever that is the case, however, there is no isolable morphemic constituent in an analysis similar to that in (5) with which the corresponding content can be identified.

Further, some relevant information may not be conveyed by any overt constituent of the form. For instance, the Georgian verb in (6) is entirely parallel to the one in (5), except that there is no overt marker of the first-person subject, because the marker we would expect (a prefixed *v-*) is mutually exclusive with the second-person object marker *g-*.

(6) mo-g-k'lav
PVB-2.OBJ-kill
'I will kill you'

Despite the lack of a formal marker, however, this verb must be considered to agree with a first-person subject. Apart from the unambiguous interpretation of (6), this can be seen from the fact that pronouns need not be phonologically overt in sentences with verbs that agree with them – including verbs for which that agreement is not itself represented by an overt marker.

The problem of nonovert markers of morphosyntactically relevant information is typically solved by positing a zero morph in the analysis of the form and then claiming that the information in question is carried by this element. In the specific case of the Georgian verb in (6), this move is actually ruled out by factors internal to the language's verbal morphology (discussed in Anderson, 1992). But in any event, as previously discussed, positing zero morphs is simply a name for this problem rather than a solution to it. The point is that there is morphosyntactic information associated with the form that is not reflected in any overt way in its phonological shape. This implies that the representation of such morphosyntactic information is more abstract than a mere analysis of its formal composition.

Such an analysis of the overt form of a word shows itself to be inadequate in other ways as well. For instance, the analysis in (5) obviously represents not only which formal components appear in the word but their linear positions relative to one another as well. If linear position is not correctly represented, the surface shape of the word cannot be produced correctly; but it is a general principle that the linear position of formatives is never relevant in itself for syntactic purposes. For instance, in the Choctaw verbs *hilha-li-h* 'I danced' vs. *ish-hilha-h* 'he danced' the subject marker appears as a suffix if it is first person but as a prefix if it is third person. No rule of syntax in any language, as far as is known, is ever sensitive to such differences; we do not find, for example, that a potentially preverbal subject pronoun can be omitted if it is third person (because linearly adjacent to the agreement marker) but not if it is first person. Where linear order appears to be syntactically relevant, as in the cases discussed by Baker (1985) as the Mirror Principle, what is really at stake is derivational scope rather than linear position itself, although these two are typically closely correlated, as Baker's paper establishes.

A morphological analysis of the overt form of a word also contains other information that is systematically irrelevant to its value as far as the syntax is concerned, such as the presence of empty morphs (e.g., the /-t-/ in Menomini *ke-t-ōs* 'your-Ø-canoe' or 'your canoe' and Romance thematic vowels) and multiple instances of the same material (as in the Dargwa *b-ī̄k'a-zi-b qalč'e* 'little bird,' where the lexical class of the head noun is reflected more than once in the adjective). The systematic irrelevance of such material for the syntax suggests that information about it should not be present at the interface between word structure and sentence or phrase structure.

The appropriate conclusion appears to be that this interface between morphology and syntax is a somewhat abstract structure: a morphosyntactic representation of the properties expressed by a word rather than a representation of its formal makeup. A-Morphous Morphology proposes that the formal nature of these structures is quite simple: essentially, they are unordered (but potentially recursive) structures composed solely of simple morphosyntactic features. The principles by which such structures are composed and referred to in grammar form an important area of inquiry within the theory.

Analytic Philosophy

M Beaney, Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

'Analytic philosophy' is the name that is given to what is now generally regarded as the dominant philosophical tradition in the English-speaking world and increasingly in the rest of the world. In its widest sense, it might be taken to mean any kind of philosophy in which analysis plays a central role. But there are all sorts of kinds of analysis, and analysis – in one form or another – has been part of philosophy since the time of the ancient Greeks. Sometimes it is characterized in terms of the emphasis placed on clarity, rigor, and careful argumentation, often involving logical formalization. This might distinguish it from some types of 'continental' philosophy (as it is misleadingly called), to which analytic philosophy is frequently seen as opposed. But the best way to understand analytic philosophy is historically, as a movement that had its roots in developments around the turn of the 20th century and evolved in various directions in response to them.

The origins of analytic philosophy lie in the work of Gottlob Frege (1848–1925), Bertrand Russell (1872–1970), G. E. Moore (1873–1958), and Ludwig Wittgenstein (1889–1951). In many ways, early analytic philosophy can be seen as comprising two main strands, one developing from Frege's logical analyses of number statements and Russell's theory of descriptions, and the other from Moore's concern with conceptual analysis in ethics and epistemology, the two strands synthesised to some extent by Wittgenstein in the *Tractatus* (1921).

Frege's Analysis of Number Statements

Central to Frege's logical analysis of number statements is the idea that number statements are assertions about concepts. A statement such as *Jupiter has four moons* is to be understood, not as predicating of Jupiter the property of having four moons, but as predicating of the concept 'moon of Jupiter' the second-level property 'has four instances,' which can be logically defined (cf. Frege, 1884: § 57). The philosophical significance of this idea can be illustrated by taking the case of negative existential statements (number statements involving the number 0), which have caused problems throughout the history of philosophy. Consider the following statement:

(U) Unicorns do not exist.

This statement is true, so it must clearly have a meaning. But what is it for (U) to have a meaning? If we analyze it in subject-predicate terms, in accord with its surface grammatical form, then 'unicorns' is the subject and 'do not exist' the predicate. But how can we say anything meaningful if 'unicorns' does not refer to anything? If unicorns do not exist, then what is it to which we are predicating the property of nonexistence? Should we posit – as Meinong and the early Russell did – the 'subsistence' of nonexistent objects to act as the subjects of statements about them? On Frege's account, however, such a statement is to be understood as asserting something, not about unicorns but about the concept of 'unicorn.' (U), in other words, really means what is better expressed as:

(U*) The concept 'unicorn' is not instantiated.

Interpreted like this, it can then be readily formalized in modern logic:

(U#) $\neg \exists x\, Fx$.

On Frege's view, existence should not be seen as a (first-level) predicate, but instead, existential statements are to be analyzed in terms of the (second-level) predicate *is instantiated*, represented by the existential quantifier. To say that something does not exist is to say that the relevant concept is not instantiated.

Russell's Theory of Descriptions

A similar strategy is employed by Russell in his theory of descriptions (1905). Consider Russell's famous example:

(K) The present King of France is bald.

(in this case, that the world is Newtonian). Quine's view that there are no analytic or *a priori* sentences was widely influential; however, there is now renewed interest in making the distinction between *a priori* and *a posteriori* assertions to better understand how scientific theories function.

Quine's attack on the analytic/synthetic distinction eventually faced empirical scrutiny. Linguists such as Noam Chomsky and Ray Jackendoff have shown that there are empirical reasons to hold that there is an analytic/synthetic distinction. Certain sentences seem to show analytic connections with one another. For instance, upon hearing the sentence 'Jane was convinced to leave' one will assume that Jane decided to leave. An analytic sentence is one whose truth is given by the existence of such a connection. Analytic sentences in this sense are true in virtue of meaning. They are also knowable independent of experience and thus *a priori*. However, that they are knowable independently of experience is not itself knowable *a priori* but known though empirical investigation of natural language. Kant imagined that we could identify *a priori* truths *a priori*. Here we have a case of *a priori* truths that are dicovered empirically. On this view *a priori* truths can have no foundational epistemological status.

It had been almost universally believed that all analytic claims were *a priori*. This position is shared by Kant and the positivists (the positivists went further in claiming that all *a priori* claims were analytic). However, on the basis of work by Saul Kripke and Hilary Putnam, a case can be made that certain claims are both analytic and *a posteriori*. That is, there are claims that are true in virtue of meaning, but are not knowable independently of experience. For instance, part of the meaning of the term 'water' is that it is composed of H_2O. So the sentence 'water is H_2O' is true in virtue of meaning, and thus analytic. However, this sentence is nonetheless a substantial claim about the world and certainly not knowable independently of experience, and thus it is *a posteriori*.

Aalto, Pentti (1917–1998)

A Parpola, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Pentti Aalto, born in 1917 in Pori (Finland), took his M.A. in Latin, Greek, Sanskrit, and Altaistics at the University of Helsinki in May, 1939. During World War II, he served in the Finnish Army as an officer charged with decoding enemy ciphers. After the war, he continued his studies, partly in Sweden, and defended his doctoral thesis in Helsinki in 1949. Aalto was Docent of Comparative Linguistics from 1949 to 1958 and Professor of Comparative Linguistics from 1958 to 1980 at the University of Helsinki.

His first major publications dealt with the history of Latin gerund and gerundive (1949) and Greek infinitive (1953). After the death of his teacher G. J. Ramstedt in 1950, Aalto edited Ramstedt's main work, a comparative grammar of the Altaic languages (1952–1966), and many of his unpublished papers. Aalto's own critical edition of the Mongolian version of the Buddhist text *Pañcarakṣā*, translated from Tibetan, appeared in 1961. Together with his student, the Latinist Tuomo Pekkanen, Aalto published an important collection (1975–1980) of Latin sources on the peoples of Northeast Asia, spanning from antiquity to the times of Charles the Great. Aalto wrote (1971–1987) the history of Oriental, classical, and modern language studies in Finland during the period of the Russian rule. A selection of the hundreds of articles and reviews written by Aalto was published in 1987.

Aasen, Ivar Andreas (1813–1896)

A Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Ivar Aasen is an iconic figure in Norwegian cultural history, regarded as one of the architects of Norwegian national identity in the 19th century. A substantial amount has been written about Aasen, much of which has been of a rather bland hagiographical nature. Three substantial biographies appeared in the centenary year of 1996 (Krokvik, 1996; Venås, 1996; Walton, 1996), which witnessed a variety of celebrations in honor of Aasen and clearly demonstrated his standing within Norwegian culture.

Although he lacked a formal education, Aasen presented himself effectively in intellectual and cultural circles, securing a grant from the Norwegian Academy of Sciences and later one from the state to pursue his investigations of Norwegian. His travels in rural parts of the country to collect dialect forms resulted in a dialect grammar, *Det norske Folkesprogs Grammatik* (1848), and a dictionary, *Ordbog over det norske Folkesprog* (1850). These works led to a later grammar (*Norsk Grammatik*, 1864) and dictionary (*Norsk Ordbog med dansk Forklaring*, 1873), which provided the basis for the written variety of Norwegian, initially known as Landsmaal and renamed Nynorsk in 1928. Although he continued to write Danish for most purposes, Aasen exemplified the use of Landsmaal himself, first in the 1849 *Conversation between two farmers* and then in book form in the 1853 *Prøver af Landsmaalet i Norge*. Far from providing a new model written variety around which Norwegians could rally, Aasen's example unleashed a variety of competing models based on different dialects, and it was not until 1901 that a standard for Landsmaal (based on Aasen) was finally sanctioned.

Aasen's skill as a dialectologist is undoubted, although his methods soon appeared dated with the emergence in Scandinavia during the 1870s of the new dialectology based firmly on phonetic principles. The collections he made, which are currently being published in a series of volumes by the Ivar Aasen Society, are an invaluable resource for the study of variation in Norwegian in the mid-19th century. It is clear that his descriptive work was based from the outset on the notion of a standard underpinning the surface variety (Walton, 1996), and his presentation of the material, particularly in the 1864 grammar, is characterized by the clever use of stylistic devices to reinforce that impression (Linn, 1997).

Although brought up in rural western Norway, Aasen spent the bulk of his adult life in the capital city, where he remained on the margins of academia, never taking up a university post. As well as various programmatic writings, he produced among other things a collection of Norwegian proverbs (*Norske Ordsprog*, 1st ed. 1856), an onomasiological dictionary (*Norsk Maalbunad*, published 1925), and a variety of literary works.

Abduction

F Merrell, Purdue University, West Lafayette, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

In addition to the traditional division of inferential reasoning into two categories, *deduction* and *induction*, Charles S. Peirce has added a third term – that of *abduction*. For Peirce, deduction is a logical inferential matter, much as tradition had it, and induction involves the process we would ordinarily term confirmation of deduced hypotheses through observation of particular cases. But how is it that hypotheses come about in the first place? Peirce surmised that there must be some process of insight, or abduction, which then leads to some hypothetical plausibility that precedes the actual logical construction of a hypothesis. This insight, he believed, must follow some style of reasoning and inference of which deductive reasoning knows little (Peirce, 1958: 7.218).

Inference can in general be *explicative* or *ampliative*. If explicative, it is analytical, involving deduction of the necessary consequence leading from a hypothesis. If ampliative, it is synthetic, involving the creation of a hypothesis by abductive inference and the subsequent confirmation of the hypothesis by means of experience in the physical world (Peirce, 1931–1935: 2.776). Abductive inference initially emerges when there is a surprise, because something other than what was expected occurred. From the surprise, creation of a plausible explanation emerges (abduction); the plausible explanation gives rise to a hypothesis to the effect that in case certain conditions were to inhere, in all such cases a certain consequence would likely ensue (deduction); and if a particular instance of that case confirms the hypothesis, then the confirmation would become what should be expected in all such cases (induction). In this sense, abduction proceeds from a present surprise to what might happen in future instances comparable to the present, deduction passes from the feeling that what might happen should happen in future instances when certain conditions are in place, and induction proceeds from what actually happened in past and present instances toward a general idea regarding all comparable instances (Peirce, 1931–1935: 2.636).

On merging abduction with his belief that feeling has its own style of reasoning, Peirce occasionally suggested that the abductive act is an instinctive capacity of the sufficiently prepared mind for informed guesses, for the mind has "a natural bent in accordance with nature" (Peirce, 1931–1935: 6.478). Can there indeed be a 'logic' for creating hypotheses? Tradition responds with an emphatic 'No.'

Karl Popper, a critic of the idea of a logical process for hypothesis making, wrote that the act of conceiving a hypothesis is not logical; it is the result of blind guesses (Popper, 1959: 20–21). Peirce, in contrast, argued that guesses are informed by the instinctive mind that has been able to get in tune with nature. Only in this manner, he believed, can we abduce what might be, from a virtually infinity of possibilities, with a remarkable degree of wisdom. Abducing what might be, then, is more a matter of instinctive cunning than mere chance. After the abductive act, the 'reasoning' mind can take over in determining what should be and what actually **is**.

Abduction

F Merrell, Purdue University, West Lafayette, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

In addition to the traditional division of inferential reasoning into two categories, *deduction* and *induction*, Charles S. Peirce has added a third term – that of *abduction*. For Peirce, deduction is a logical inferential matter, much as tradition had it, and induction involves the process we would ordinarily term confirmation of deduced hypotheses through observation of particular cases. But how is it that hypotheses come about in the first place? Peirce surmised that there must be some process of insight, or abduction, which then leads to some hypothetical plausibility that precedes the actual logical construction of a hypothesis. This insight, he believed, must follow some style of reasoning and inference of which deductive reasoning knows little (Peirce, 1958: 7.218).

Inference can in general be *explicative* or *ampliative*. If explicative, it is analytical, involving deduction of the necessary consequence leading from a hypothesis. If ampliative, it is synthetic, involving the creation of a hypothesis by abductive inference and the subsequent confirmation of the hypothesis by means of experience in the physical world (Peirce, 1931–1935: 2.776). Abductive inference initially emerges when there is a surprise, because something other than what was expected occurred. From the surprise, creation of a plausible explanation emerges (abduction); the plausible explanation gives rise to a hypothesis to the effect that in case certain conditions were to inhere, in all such cases a certain consequence would likely ensue (deduction); and if a particular instance of that case confirms the hypothesis, then the confirmation would become what should be expected in all such cases (induction). In this sense, abduction proceeds from a present surprise to what might happen in future instances comparable to the present, deduction passes from the feeling that what might happen should happen in future instances when certain conditions are in place, and induction proceeds from what actually happened in past and present instances toward a general idea regarding all comparable instances (Peirce, 1931–1935: 2.636).

On merging abduction with his belief that feeling has its own style of reasoning, Peirce occasionally suggested that the abductive act is an instinctive capacity of the sufficiently prepared mind for informed guesses, for the mind has "a natural bent in accordance with nature" (Peirce, 1931–1935: 6.478). Can there indeed be a 'logic' for creating hypotheses? Tradition responds with an emphatic 'No.'

Karl Popper, a critic of the idea of a logical process for hypothesis making, wrote that the act of conceiving a hypothesis is not logical; it is the result of blind guesses (Popper, 1959: 20–21). Peirce, in contrast, argued that guesses are informed by the instinctive mind that has been able to get in tune with nature. Only in this manner, he believed, can we abduce what might be, from a virtually infinity of possibilities, with a remarkable degree of wisdom. Abducing what might be, then, is more a matter of instinctive cunning than mere chance. After the abductive act, the 'reasoning' mind can take over in determining what should be and what actually **is**.

Abercrombie, David (1909–1992)

J Kelly, Leeds, UK

© 2006 Elsevier Ltd. All rights reserved.

David Abercrombie, a British phonetician, was responsible for establishing and directing the Department of Phonetics at the University of Edinburgh, a major European center of work in the discipline during the latter half of the 20th century.

Abercrombie was born in Birkenhead, Cheshire. After study under Daniel Jones at University College, London, and at the Institut de Phonétique in Paris, he worked briefly at the London School of Economics and then in an English teaching post with the British Council, which took him to Greece and Egypt during the years of World War II. On his return to Britain, a short spell at the University of Leeds led to his move to Edinburgh in 1948 to take up the headship of the newly founded Department of Phonetics. He was to spend the rest of his career in Edinburgh, retiring as Professor of Phonetics in 1980, and it was there that he died.

His department was just one of a number of establishments in the university dedicated to the language sciences that were brought into being during the years following World War II. Others were a Department of General Linguistics, a School of Applied Linguistics, and the Linguistic Survey of Scotland. The theoretical outlook of all of these was unified to quite a considerable degree since many members of their staffs had been students in London under J. R. Firth. Abercrombie himself had come under Firth's influence when a student at University College, where Firth held his first London teaching post between 1928 and 1938; and the Edinburgh Phonetics Department was to include other teachers who had studied either at University College or at the London School of Oriental and African Studies. By the time of Abercrombie's retirement, the three teaching departments had amalgamated.

Abercrombie saw his subject as in no way an adjunct to language teaching and learning, a position to which it could sometimes be relegated in universities, but as an independent discipline of long pedigree with manifold connections into, and implications for, other disciplines and a wide range of applications in everyday life and in the world of work. The sets of courses that he designed for his department reflected his interests and convictions. He had an unrivaled knowledge of several centuries of work in phonetics, gathered from assiduous reading in the British Museum during his student days, and was often able to point out in discussion that this or that 'new' idea, technique, or technical term was not, in fact, all that new. From this early study arose his belief that some knowledge of the history of the subject was an indispensable part of the

David Abercrombie, a British phonetician, was responsible for establishing and directing the Department of Phonetics at the University of Edinburgh, a major European center of work in the discipline during the latter half of the 20th century.

Abercrombie was born in Birkenhead, Cheshire. After study under Daniel Jones at University College, London, and at the Institut de Phonétique in Paris, he worked briefly at the London School of Economics and then in an English teaching post with the British Council, which took him to Greece and Egypt during the years of World War II. On his return to Britain, a short spell at the University of Leeds led to his move to Edinburgh in 1948 to take up the headship of the newly founded Department of Phonetics. He was to spend the rest of his career in Edinburgh, retiring as Professor of Phonetics in 1980, and it was there that he died.

His department was just one of a number of establishments in the university dedicated to the language sciences that were brought into being during the years following World War II. Others were a Department of General Linguistics, a School of Applied Linguistics, and the Linguistic Survey of Scotland. The theoretical outlook of all of these was unified to quite a considerable degree since many members of their staffs had been students in London under J. R. Firth. Abercrombie himself had come under Firth's influence when a student at University College, where Firth held his first London teaching post between 1928 and 1938; and the Edinburgh Phonetics Department was to include other teachers who had studied either at University College or at the London School of Oriental and African Studies. By the time of Abercrombie's retirement, the three teaching departments had amalgamated.

Abercrombie saw his subject as in no way an adjunct to language teaching and learning, a position to which it could sometimes be relegated in universities, but as an independent discipline of long pedigree with manifold connections into, and implications for, other disciplines and a wide range of applications in everyday life and in the world of work. The sets of courses that he designed for his department reflected his interests and convictions. He had an unrivaled knowledge of several centuries of work in phonetics, gathered from assiduous reading in the British Museum during his student days, and was often able to point out in discussion that this or that 'new' idea, technique, or technical term was not, in fact, all that new. From this early study arose his belief that some knowledge of the history of the subject was an indispensable part of the

formation of all postgraduate students in phonetics – this at a time when many took the beginnings of the subject to stretch back barely further than the turn of the century.

Another important area of his department's teaching at both the under- and postgraduate levels was the laying down of a solid base of practical phonetic skills. The first-year undergraduate course of 5 hours a week included 1 hour each of performance and ear-training and a weekly transcription exercise. Students were expected to transcribe their own English, and the staff paid much attention to helping them elaborate valid transcriptions, especially necessary given the wide range of Scots accents represented in the student body.

Research and teaching in Abercrombie's department always proceeded on the understanding that phonetics and phonology were two sides of the same coin, a stance common throughout the development of a linguistics tradition in Britain, and well personified in Firth, who was probably more a mentor to Abercrombie than was Jones. Postgraduate students were routinely sent to undertake supervised work on the Survey of Scottish Dialects, an experience meant to stretch and benefit them in their capacities as both phoneticians and phonologists. Despite this emphasis in the department, though, and rather surprisingly given his London University training, Abercrombie himself rarely ventured into serious work in any area of phonology.

His writings, though not abundant, are notable for concision and clarity, and reflect the wide range of his interests. In addition to publications on the history of the subject, there are papers on speech rhythm and stress, terminology, transcription theory, English accents, and various matters of practice in phonemic phonology. Abercrombie always included some first-year undergraduate teaching among his commitments as a matter of principle; and his *Elements of general phonetics* derives from his teaching of the department's first-year undergraduate course. It is too idiosyncratic and selective to make an ideal textbook, but displays well the lucid and uncluttered prose style, quite free of jargon, that makes his writing attractive and accessible.

Abercrombie's qualities extended beyond his abilities and achievements as a teacher and writer. Totally at home in academia (his father had held a chair at London University), polished and unfailingly courteous, he made a most able and prepossessing public relations officer for phonetics, combining a measure of shrewdness with diplomacy and great ease of manner in his mission to support and further the work of his department and the careers of his colleagues and students. His home served in some ways as an extension of the Phonetics Department, since he and his wife held open house on Sunday mornings for many years, not only for departmental colleagues and postgraduate students but also for colleagues from other departments where there might be shared interests, such as music or physiology, and for overseas linguists and phoneticians visiting Britain, who unfailingly included Edinburgh in their itineraries. It was at such gatherings that staff and students might meet, say, Pike, Martinet, or Jacobson for the first time.

In 1991 he was elected, as his father had been before him, to the British Academy.

Abkhaz

B G Hewitt, SOAS, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Abkhaz language (/[ɑ.]ˈɑps.(wɑ bəz.ˈ)ʃʷɑ/) belongs to the North West Caucasian family (*see* **Caucasian Languages**). Abkhazians traditionally occupied the triangle framed in northwestern Transcaucasia between the Black Sea, the Greater Caucasus, and the river Ingur; the river Psou is now the northern frontier. This territory comprises the Republic of Abkhazia (/ɑ.ps.ˈnə/, capital Aqʷ'a, aka Sukhum), *de facto* independent since the war with Georgia (1992–1993) but in international law,

deemed to be part of Georgia still. For most of the Soviet period it was an autonomous republic.

A wave of migrants out of Abkhazia after the Mongol incursions (14th century) removed the most divergent dialect, T'ap'anta, to the northern Caucasus (Karachay-Cherkessia). Consolidated there by Ashkharywa dialect speakers (17th and 18th centuries), today's Abaza population descended from them. Following Russia's conquest of the northwest Caucasus in 1864, most North West Caucasian speakers (including the now extinct Ubykhs) migrated to Ottoman lands, where the diaspora-communities (predominantly in Turkey) vastly outnumber the homelanders; even so, the surviving languages are endangered in all locations. The dialects of Sadz, Akhch'ypsy, and Ts'abal are no longer attested in Abkhazia; only northern Bzyp and southern Abzhywa remain. Of the 102 938 Soviet Abkhazians recorded in 1989, 93 267 resided in Abkhazia, constituting 17.8% of the population. The single largest ethnic group in Abkhazia in 1989 were the Mingrelians; Abazas totalled 33 801. Though 93.3% of Abkhazians claimed fluency in Abkhaz, younger generations tend to use Russian (or Turkish).

The 17th-century, half-Abkhazian traveller Evliya Çelebi provided the first linguistic evidence. P. Uslar produced the first grammar (1862–1863), devising a Cyrillic-based script. An adaptation of this alphabet served the Abkhazians when the Soviets assigned them literary status (1921), though two different roman orthographies were tried during the infant USSR's *latinizatsija*-drive. A Georgian orthography was imposed in 1938 and replaced by another Cyrillic alphabet in 1954. This one is still used, albeit with a recent reform to regularize labialization-marking. Abaza acquired literary status only in 1932; the Abkhaz and Abaza Cyrillic scripts diverge markedly.

A comprehensive list of phonemes appears in Table 1.

Certain idiolects have /f'/ only in /ɑ.ˈf'ɑ/ 'thin' (otherwise /ɑ.ˈp'ɑ/). Bzyp boasts 67 phonemes by adding /ʧ͡ ʤ͡ ʧ͡' ɕ ʑ ɕʷ ʑʷ/ to the alveolo-palatals and /χˤ χˤʷ/ to the back fricatives. A glottal stop, apart from possibly realizing intervocalic /q'/, is also heard in /ʔɑj/ 'no' (cf., /ɑːj/ 'yes'). Open vowel /ɑ/ contrasts with close /ə/; /ɑː/ might also be phonemic. Stress is distinctive.

Abkhaz(-Abaza) is unique among Caucasian languages in not employing case-markers for the verb's major arguments, relying purely on pronominal crossreferencing within the polysynthetic verb; this patterning with three sets of affixes confirms the family's ergative nature. Some preverbs distinguish directionality via an a-grade (essive/illative/allative) vs. a reduced/zero grade (elative/ablative) for the specified location.

Table 1 Consonantal phonemes for literary (Abzhywa) Abkhaz

Roy Clive Abraham (1890–1963), born in Melbourne, Australia, was a major figure in the study of African languages during the 20th century, publishing dictionaries and grammars on a wide range of languages within the Afroasiatic and Niger-Congo families. Educated at Balliol College, University of Oxford, he was awarded a first-class honors degree in Oriental Languages in 1924 (Arabic and Persian), followed by a certificate in Anthropology from University College, London, and a diploma in Classical Arabic from the School of Oriental and African Studies (SOAS), University of London.

Abraham’s first experience of sub-Saharan Africa was in 1925, when he entered the administrative service of the northern provinces of Nigeria. He continued in the colonial service until 1944. In 1926, he conducted his first independent research on an African language, working on Bole (Bolanci), a small West Chadic (Afroasiatic) language closely related to Hausa. He then assisted G. P. Bargery in the preparation of the latter’s colossal *Hausa-English dictionary* (1934). Abraham had learned about the contrastive function of tone in West African languages from Bargery, and in his *The principles of Hausa* (1934) he simplified Bargery’s erroneous 6-tone system to Hausa’s correct 3-tone system. During this especially productive period he also completed grammars on two Niger-Congo languages spoken in Nigeria: *The grammar of Tiv* (1933) and *The principles of Idoma* (1935). In 1949 he was awarded a D.Litt. by the University of Oxford on the basis of three of his publications on Tiv. Subsequent works included his *Dictionary of the Hausa language* (1949, with Mai Kano), and *The principles of Somali* (1951, with Solomon Warsama).

Abraham then embarked on a study of Yoruba, having made his own way to Ibadan, Nigeria, and produced his *Dictionary of Modern Yoruba* (1958). Although the quality of his prolific output varied – some of the descriptions and analyses in his reference grammars, for example, contain sharp insights, others are opaque in parts – when judged in their entirety, Abraham’s influential publications represented major empirical and analytical advances in the study of African languages.

Abraham was sometimes difficult and temperamental, and his relations with colleagues and peers could be turbulent. His relationship with Bargery in particular became increasingly frosty after their early collaboration on Bargery’s *Hausa-English dictionary*, and in 1946 he failed in his bid to succeed Bargery to the SOAS Hausa post. (The position was given instead to F. W. Parsons, who went on to become the leading Hausa scholar in the postwar period.) He was subsequently appointed to a new lectureship in Amharic, however, a post he held until he retired in 1951.

Although suffering from poor health in later years, Abraham’s drive and scientific predisposition led him to turn his attention to yet another Nigerian

Abstraction

E Mathieu, University of Ottawa, Ottawa, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Abstraction in linguistics is very common and is pervasive not only at high levels of theoretical analysis but also, and crucially, at basic levels of description. This is because as soon as one generalizes from/over data or recurrent patterns, one is bound to want to use abstract features as shorthand. In other words, this is abstraction as methodology.

To give a definition of abstraction, we can say that it is the process of recognizing among a number of entities some common feature and, on that basis, forming the concept or the generalization of that feature. As a way of illustration, consider the following examples:

(1) Rufus loves Candice.

(2) Michelle loves Brent.

(3) Knut loves Pim.

(4) Alicia loves Fleur.

The verb *love* in English (and in other languages) involves a relation between a lover and a 'lovee.' We say that the lover and the loved one are arguments of the verbs, and as they can be arbitrary (all sorts of people can love each other – Rufus, Candice, Michelle, Brent, Knut, Pim, Alicia, and Fleur in our case), we can abstract away from Rufus and his friends and simply write (5), in which x = any lover and y any 'lovee.' Thus, here we already attained a certain degree of abstraction.

(5) love (x, y)

Noticing further that a relation between x and y does not have to be about love but could be about other predicates such as *hate*, *admire*, or *kill*, we can go even farther in the degree of abstraction for the representation of verbs and their arguments. We can have P standing for predicate, as illustrated in (6):

(6) $P(x, y)$

What the formula (6) says is that there is a predicate P (i.e., any predicate) that takes two arguments. The terms P, x, and y are called variables, or in other words, abstractions of instantiations of entities. Note that the variables x and y in (6) are free. There is one way to bind these variables in linguistics and logic that is quite useful – by λ abstraction. Adding the λ operator to predicate logic makes it possible to construct predicates from formulae with free variables. Suppose we know John is in love; the example in (7) means that we have a predicate that denotes the property of being loved by John.

(7) λx [love (John, x)]

language, Igbo, and he was preparing a dictionary and grammar on the language when he died at his home in London on June 22, 1963, at the age of 72. He was survived by his wife Sadie and son Donald. A commemorative volume in recognition of his outstanding contribution to the study of African languages was published in 1992.

Abstraction

E Mathieu, University of Ottawa, Ottawa, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Abstraction in linguistics is very common and is pervasive not only at high levels of theoretical analysis but also, and crucially, at basic levels of description. This is because as soon as one generalizes from/over data or recurrent patterns, one is bound to want to use abstract features as shorthand. In other words, this is abstraction as methodology.

To give a definition of abstraction, we can say that it is the process of recognizing among a number of entities some common feature and, on that basis, forming the concept or the generalization of that feature. As a way of illustration, consider the following examples:

(1) Rufus loves Candice.

(2) Michelle loves Brent.

(3) Knut loves Pim.

(4) Alicia loves Fleur.

The verb *love* in English (and in other languages) involves a relation between a lover and a 'lovee.' We say that the lover and the loved one are arguments of the verbs, and as they can be arbitrary (all sorts of people can love each other – Rufus, Candice, Michelle, Brent, Knut, Pim, Alicia, and Fleur in our case), we can abstract away from Rufus and his friends and simply write (5), in which x = any lover and y any 'lovee.' Thus, here we already attained a certain degree of abstraction.

(5) love (x, y)

Noticing further that a relation between x and y does not have to be about love but could be about other predicates such as *hate*, *admire*, or *kill*, we can go even farther in the degree of abstraction for the representation of verbs and their arguments. We can have P standing for predicate, as illustrated in (6):

(6) $P(x, y)$

What the formula (6) says is that there is a predicate P (i.e., any predicate) that takes two arguments. The terms P, x, and y are called variables, or in other words, abstractions of instantiations of entities. Note that the variables x and y in (6) are free. There is one way to bind these variables in linguistics and logic that is quite useful – by λ abstraction. Adding the λ operator to predicate logic makes it possible to construct predicates from formulae with free variables. Suppose we know John is in love; the example in (7) means that we have a predicate that denotes the property of being loved by John.

(7) λx [love (John, x)]

If, however, we leave the variable corresponding to John in the formula in (7) free, and we let the λ operator bind it, as in the formula in (8), then the expression denotes the property of 'John being loved,' which is equivalent to the passive form, 'John is loved' (i.e. 'by someone'; we don't know whom exactly). On λ abstraction, see Heim and Kratzer (1998) and the references cited therein.

(8) λx [love (x, John)]

It is easy to see from examples such as (7) and, especially, (8) that we use abstract entities all the time. When we use a passive instead of an active form, it is because we do not know to who or what the entity is referring exactly (as in 'John is loved,' 'Sam was attacked'). We can thus refer to abstract entities, which do not necessarily have any concrete objects in relation to them. This is useful for thinking and communication, as one is not tied to the world of concrete things.

In generative grammar, examples of abstract entities include subjects of infinitives, represented by PRO as in sentence (9), abstract Case as in sentence (10), and abstract Infl as in sentence (11).

(9) John wanted PRO to go shopping.

(10) John bought a book.

(11) I love tennis.

In this case, PRO is taken to be the subject of an infinitival verb. In the case of sentence (9), PRO refers to the subject of the main clause 'John.' The person who is doing the wanting and who is doing the shopping is the same. In sentence (10), the constituent 'a book' receives the accusative Case. In English, it is assumed that although there is no morphological realization of case, it is nevertheless present abstractly. Sentence (11) shows that English does not exhibit inflection (agreement) on verbs such as 'love' with the first-person singular. However, as many other languages do, abstract inflection (agreement) is postulated for languages like English.

Evidence for the claim that subjects of infinites are represented by empty categories such as PRO comes from the distribution of the *want + to* contraction in English (on *wanna* contraction see early work by Lakoff (1970) and Selkirk (1972), and then Van Riemsdijk and Williams (1986) and Lasnik and Uriagereka (1988), and for experimental research on the topic, see Crain and Lillo-Martin (1999), together with the references cited therein). In many dialects of English, either sentence (12a) or sentence (12b) is possible:

(12a) I want to go shopping.
(12b) I wanna go shopping.

However, when we ask a question, such as in sentence (13b), corresponding to the statement in sentence (13a), and in which *who* is extracted from the embedded clause, it is impossible to contract *want + to*, as shown in sentence (13c). This has often been taken to indicate that there is an empty category without phonological realization, but with full syntactic status, intervening between *want* and *to* (namely, PRO).

(13a) I want John to go shopping.
(13b) Who do you want to go shopping?
(13c) *Who do you wanna go shopping?

Turning now to case, although (as has been already mentioned) the constituent *a book* in sentence (10) bares no overt case (as it would, say, in German), it is a general consensus in generative grammar that the direct object bears abstract Case (in this instance, accusative Case, with the capital C being a special notation for the abstract nature of the case). Evidence for the hypothesis that even in English the direct object receives accusative from the verb comes from the fact that it is not possible to split the verb from the object in that language. On the assumption that the accusative case, and cases in general, are assigned by the relevant elements in the grammar in a strict local fashion (i.e., the notion of government, found in traditional grammar and in the government and binding framework of Chomsky [1981]), the blocking effect is explained by the fact that the verb in this instance cannot assign a Case to its object:

(14a) *John buys never socks.
(14b) John never buys socks.

Finally, evidence for the idea that abstract inflection is present in examples such as sentence (11) comes from the fact that an alternative to sentence (11) is available and illustrated in sentence (15):

(15) John does love tennis.

In the right context, sentence (15) would be used for emphasis. Here, we note that a third-person singular inflection surfaces in the form of *does* (the other form of *do* being simply *do*, as in *we do love tennis* or *I do love tennis*). On the inflection and parametric variation, see Pollock (1989).

It is one thing to postulate that abstract entities or symbols are representations of real-life entities for ease of data description or presentation of generalizations; it is another to claim that abstraction is at the core of human language and that the object of study in linguistics is an abstraction from real language data. However, this is exactly what both structuralists and generativists have done. It must be noted that generative models place heavy emphasis on the

reality of these abstractions. Abstract patterns are supposed to be psychologically real and present in the mind–brain. This is very different from the traditional or classical structuralist stance, according to which language is not tied to any psychological reality.

Academies: Dictionaries and Standards

L C Mugglestone, Pembroke College, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

National language academies had their beginning in the Renaissance, when the first such academy, the Italian Accademia della Crusca, was founded in 1584. The Académie Française followed in 1635, and the Real Academia Española in 1713, establishing a tradition which has continued into the 20th century; the Hebrew Language Academy was, for example, founded in 1953. Academies of this kind have typically been constituted as influential and authoritative bodies that have, as part of their remit, the maintenance and regulation of individual languages. The production of a dictionary has frequently been given as a major objective in their foundation, particularly since dictionaries (especially in the past) have often been seen as a central means by which issues of language maintenance could be realized. Academy dictionaries are, as a result, characteristically engaged in the conscious processes of standardization and the codification of preferred norms of usage.

The Accademia della Crusca and the First Academy Dictionary

The origin of the move to establish national language academies can be located in the Italian Accademia della Crusca. Its remit was explicitly prescriptive, and the dictionary which it eventually published in 1612 – the *Vocabulario degli accademicia della Crusca* – embodied these aims; the words it recorded are those which can be supported by the written authority of great works, rather than by the evidence of then-current usage (especially spoken usage). Lexical innovation was tolerated only where it was felt to be unavoidable, and both patriotism and purism informed the principles of lexical selection which were employed. The dictionary was particularly inspired by the attempt to remedy perceived 'degeneration,' which had taken place since the 'Golden Age' of the 14th century by means of the unwarranted processes of linguistic change. Significantly, it also sought to reflect a new concept of the vernacular as a language in its own right, rather than Italian being seen as merely a debased form of Latin. Its linguistic concerns were therefore both normative and conservative; the *Vocabulario* was felt to be the preserve only of the best usage and, more specifically, the best literary usage.

The French Academy

The methodological principles of the Académie Française also endorsed the role of the academy dictionary as linguistic exemplar. One of its founding tenets was the intention "to labour with all possible diligence to give definite rules to our language, and to

reality of these abstractions. Abstract patterns are supposed to be psychologically real and present in the mind–brain. This is very different from the traditional or classical structuralist stance, according to which language is not tied to any psychological reality.

National language academies had their beginning in the Renaissance, when the first such academy, the Italian Accademia della Crusca, was founded in 1584. The Académie Française followed in 1635, and the Real Academia Española in 1713, establishing a tradition which has continued into the 20th century; the Hebrew Language Academy was, for example, founded in 1953. Academies of this kind have typically been constituted as influential and authoritative bodies that have, as part of their remit, the maintenance and regulation of individual languages. The production of a dictionary has frequently been given as a major objective in their foundation, particularly since dictionaries (especially in the past) have often been seen as a central means by which issues of language maintenance could be realized. Academy dictionaries are, as a result, characteristically engaged in the conscious processes of standardization and the codification of preferred norms of usage.

The Accademia della Crusca and the First Academy Dictionary

The origin of the move to establish national language academies can be located in the Italian Accademia della Crusca. Its remit was explicitly prescriptive, and the dictionary which it eventually published in 1612 – the *Vocabulario degli accademicia della Crusca* – embodied these aims; the words it recorded are those which can be supported by the written authority of great works, rather than by the evidence of then-current usage (especially spoken usage). Lexical innovation was tolerated only where it was felt to be unavoidable, and both patriotism and purism informed the principles of lexical selection which were employed. The dictionary was particularly inspired by the attempt to remedy perceived 'degeneration,' which had taken place since the 'Golden Age' of the 14th century by means of the unwarranted processes of linguistic change. Significantly, it also sought to reflect a new concept of the vernacular as a language in its own right, rather than Italian being seen as merely a debased form of Latin. Its linguistic concerns were therefore both normative and conservative; the *Vocabulario* was felt to be the preserve only of the best usage and, more specifically, the best literary usage.

The French Academy

The methodological principles of the Académie Française also endorsed the role of the academy dictionary as linguistic exemplar. One of its founding tenets was the intention "to labour with all possible diligence to give definite rules to our language, and to

render it pure." Its own dictionary, published in 1640, is shaped by these concerns for linguistic propriety; it recorded only those usages felt to be truly representative of *le bel usage*. Like the *Vocabulario*, the French Academy dictionary is above all a lexicon of the written and formal language. Literary authority (of the best authors) was used to sanction and legitimize the introduction of words, with the result that archaic terms were often admitted to the exclusion of newer ones. As the preface to the seventh edition of 1877 records, "A word is not dead because we no longer employ it, if it lives on in the works of a Molière." Many of the founding authoritarian principles were maintained throughout the various editions of the dictionary (though see further below); the preface to the second edition of 1718, for example, made explicit its decision to exclude words such as *fichu*, *ratafia*, *bizarre*, and *sabler*; that of 1877 likewise noted that words which seem ill-composed or contrary to the 'genius of the language' had not been admitted. In this way, the academy dictionary can become not a dictionary of the language in itself, but instead a dictionary of the words felt to merit existence in that language.

Proposals for an English Academy

The standardizing ideals which were prominent in the French and Italian academies naturally exerted their influence upon England too. Writers such as Simon Daines (1640) publicly lamented the linguistic neglect that the absence of a corresponding academy in England seemed to suggest. Daniel Defoe, in his *Essay upon projects* (1697), urged the creation of a legislative body that would "polish and refine the English tongue, and advance the so much needed faculty of correct language ... to purge it from all the irregular additions that ignorance and affectation have produced." Though much debated, and endorsed by writers such as Jonathan Swift, Defoe's plan was never realized. Samuel Johnson's two-volume *Dictionary of the English Language* of 1755 was hailed by many (such as the actor David Garrick) as the English equivalent of the *Dictionnaire* of the Académie Française. Nevertheless, the *Dictionary* itself was tempered by Johnson's own understanding of the futility that underpins the aims of academies to control linguistic change. As he stated in the preface: "With this hope, however, academies have been instituted, to guard the avenues of their language, to retain fugitives, and to repulse intruders; but their vigilance and activity have hitherto been in vain; ... to enchain syllables, and to lash the wind, are equally the undertakings of pride, unwilling to measure its desires by its strength."

Academies in the Modern Period

The rise of descriptive linguistics in the 19th century and afterwards led to the recognition that language change cannot be halted, nor can a cordon be drawn around an individual language to protect it from undue influence from elsewhere. Lexicographical developments during the 20th century have regularly reflected this fact, though academy dictionaries can still lag behind in line with their intended regulatory function. The preface to the French *Dictionnaire* of 1935, for example, still noted that while new words had been admitted, they were only those which had been judged to be of sufficient dignity to merit such inclusion. The ninth edition of the dictionary is currently in preparation, with *A–Enzyme* being published in 1992, and *Éocène–Mappemonde* in 2000. While distancing itself from earlier attempts to fix linguistic usage, the emphasis of the Academy now falls onto maintaining the distinctive qualities of French and, in particular, to resisting the influx of anglicisms, especially in the spheres of new technologies and science. As a result, *baladeur* is preferred to *walkman*, and *logiciel* is to be used instead of *software*, while *computer* is to be rendered as *l'ordinateur*. Purism of this kind becomes the new prescriptivism in the stated aim "to defend the French language" from the incursions of the Anglophone world. Other academies, such as that of Spain, can likewise still receive criticism for their perceived elitism and conservatism in matters of usage.

Language academies, and the dictionaries they produce, are often normative and regulatory, seeking to sanction preferred usages (traditionally those based in formal, literary contexts) and to proscribe others which, for various reasons, may be seen as less favored. Beginning in the Renaissance with the Italian Accademia della Crusca and extending to many nation-states (though not Great Britain), the role of the academy has often been explicitly interventionist, especially in terms of the legitimization of new words and meanings or, as with the current concerns of the Académie Française, in the attempt to restrain the influence of the Anglophone world in the lexis of science and technology.

Accent

P Trudgill, Université de Fribourg, Fribourg, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Accent refers to speakers' segmental and nonsegmental phonetics and phonology. As a technical term, accent thus refers to the way in which people pronounce when they speak. Speaking necessarily involves pronouncing, so everybody by definition speaks with an accent, although it is common in everyday lay use to employ the term as if it applied only to people other than oneself.

Accents are most often recognized as distinct, named varieties, spoken by particular groups of people, such as Cockney (London), Scouse (Liverpool), Australian, or New York City. These four terms relate to where their speakers come from geographically, but accents may also be perceived as relating to a speaker's social background. For example, speakers may be said to have lower-class accents or aristocratic accents. In fact, however, accents are generally simultaneously both social and geographical. And, in the case of both geography and social background, in spite of the perception that named accents constitute distinct varieties, what linguistic analysis most usually reveals are continua of geographical and social accents, with no sharp dividing line between them.

An accent may also relate to whether or not someone is a native speaker of a language. Someone speaking English might be said to be doing so with a French accent, or simply with a foreign accent. This happens because the vast majority of adult and adolescent foreign language learners transfer phonetic features from their native language to the foreign language.

British linguists typically distinguish accent from dialect, where dialect may refer to pronunciation but crucially also to grammar and vocabulary (Wells, 1982; Trudgill, 2000). Normally, accent and dialect go together, so that, say, Yorkshire dialect is always spoken with a Yorkshire accent. But in Britain it is helpful to make the distinction because the highest status dialect, Standard English, is not always combined with the highest status accent, Received Pronunciation (RP). RP speakers always speak Standard English, but the reverse is by no means necessarily the case. RP is highly unusual in that, in England, it is entirely nonregional. A speaker with an RP accent cannot be identified as coming from any particular locality.

Accent, a typically group phenomenon, should be distinguished from voice, an individual phenomenon. The quality of an individual's voice depends on his or her anatomy and physiology, which is why it is possible to recognize speakers from their voices alone. However, there is a complication here. Speakers do have some control over how they use the vocal apparatus they are born with, and there is a link between accent and voice in that some regional and social accents are spoken with a recognizably particular type of voice setting. Some conservative RP speakers, for example, speak with depressed larynx voice, which means that they habitually and unconsciously lower their larynx from the neutral position when they are speaking.

Accessibility Theory

M Ariel, Tel Aviv University, Tel Aviv, Israel

© 2006 Elsevier Ltd. All rights reserved.

Natural discourse does not start from scratch. Speakers routinely integrate new information with contextual assumptions, roughly, information that they can take for granted, and so they need not assert it (Sperber and Wilson, 1986/1995). Referring to discourse entities, an inherent feature of human interactions, is no different. Although some discourse entities are (treated as) new (*a kiss* in [1]), most are (treated as) identifiable (e.g., *the review, Helen, her* in [1], and *her heart*, a first-mention, in [2]). Thus, part of the nonasserted material is information about discourse entities that the speaker would like the addressee to retrieve (for citations of SBC [Santa Barbara corpus], see Du Bois *et al.,* 2000, 2003. [...] = a short fragment deleted):

(1) LORI: when you were reading **the review**,
you talked about **the affair between Helen and Paul**, [...]
all that happened was,
LINDA: was **a kiss**. [...]
LORI: **He** kissed **her**, (SBC: 023).

(2) DORIS: they had an autopsy done on her.
And **her heart**,
was just hard, (SBC: 001).

Accessibility Theory (Ariel, 1985a, 1985b, 1988a, 1990, 2001), in effect a development of Sanford and Garrod (1981) and Givón (1983) (and see also Chafe, 1994), assumes a logically prior distinction between identifiable/Given entities (coded as definite) and nonidentifiable/Given entities (coded as indefinite). Identifiable entities are ones for which the addressee is assumed to be able to access mental representations (see Du Bois, 1980; Heim, 1982). Accessibility theory seeks to account for the selection and interpretation of all definite referring expressions. The theory does not assume (as fundamental) the first versus subsequent mention distinction, and provides one and the same account for expressions considered referential (e.g., proper names), often used for discourse first-mentions, as well as for expressions considered anaphoric (e.g., pronouns), often used for subsequent mentions (Ariel, 1990, 1994, 1996). It also does not view references to the speech situation (e.g., by deictics) as special (Ariel, 1998a). All definite referring expressions in all languages are analyzed as accessibility markers, as instructions to the addressee on how to access specific mental representations. In fact, the theory handles other types of Given materials as well, most notably whole propositions (see Ariel, 1985a, 1985b, 1988b).

Using a definite NP, the speaker signals to her addressee to access some mental representation based either on his encyclopedic knowledge, his awareness of the speech situation, or his discourse model of the interaction so far (Clark and Marshall, 1981). The definite referring expression also provides information about the intended entity, which the addressee is to rely on when zeroing in on the intended referent (e.g., *her* is a singular female). This is as far as the definiteness aspect takes us, but speakers can be even more helpful. Mental representations are not equally accessible to us at any given stage of the discourse. Some are highly activated, others are mildly activated, and yet others, although potentially identifiable, are not currently activated at all. Speakers refer to discourse entities at all activation levels. This is where accessibility theory plays a crucial role. It helps the addressee pick the correct mental representation by indicating to him the degree of accessibility with which the mental representation is currently entertained. The claim is that each referring expression specializes for a specific degree of mental accessibility, hence the term *accessibility markers* for referring expressions. On this view, addressees search mental representations not only based on the content of the referring expression, but also based on the degree of accessibility indicated by the speaker.

Since mental accessibility comes in a rich array of degrees, accessibility markers can be graded on a scale of accessibility marking, some indicating very low degrees of mental accessibility, others indicating various intermediate and high degrees of accessibility. The following partially grammaticized (see Ariel, 2001) accessibility marking scale, starting with very low accessibility markers and ending with extremely high accessibility markers, has been proposed in Ariel (1990), but the list is not intended to be exhaustive:

(3) Full name + modifier > full name > long definite description > short definite description > last name > first name > distal demonstrative + modifier > proximate demonstrative + modifier > distal demonstrative + NP > proximate demonstrative + NP > distal demonstrative (-NP) > proximate demonstrative (-NP) > stressed pronouns + gesture > stressed pronoun > unstressed pronoun > cliticized pronoun > verbal person agreement markers > zero.

For example, *the affair between Helen and Paul* in (1) is a long definite description. The prediction is that it indicates a mental representation that is not as accessible as the shorter *the review* or *he*. Indeed, *the review* is what the interlocutors have been

discussing. But the affair, as such, was not explicitly mentioned in the conversation, and in fact, according to Lori, it's not even clear that there was one. *He* (a pronoun) refers to the highly accessible Paul, who was just mentioned.

Now, the correlations between specific referring expressions and specific degrees of mental accessibility are not arbitrary. This is why (3) is virtually a universal. By and large, the accessibility marking scale is governed by three coding principles: informativity, rigidity, and attenuation. Informativity predicts that more informative expressions be used when the degree of accessibility is relatively low. It is only reasonable for the speaker to provide the addressee with more information if the mental representation is not (highly) activated, so he can better identify the intended entity from among the many he entertains at a low degree of accessibility. Rigidity predicts that a (more) uniquely referring expression (such as a proper name), rather than a relatively nonrigid expression (such as a pronoun), should be used when degree of accessibility is low (cf. *Helen*, *Paul* with *her*, *he* in [1]). Finally, attenuation predicts that greater phonological size (including the presence of stress) correlates with lower degrees of accessibility, whereas smaller phonological size correlates with higher degrees of accessibility (cf. definite descriptions vs. pronouns, and even more so with zero).

The three principles overlap to a large extent. Quite often, informative expressions are also relatively rigid and unattenuated. However, this is not invariably so. *The newspaper* and *United States of America* are as informative and rigid as *the paper* and *US*(*A*), respectively, but they are not as attenuated. Accordingly, the lower accessibility markers are found in contexts where a lower degree of accessibility is the case (see Ariel, 2001, *inter alia*). Similarly, in languages with verbal person agreement, there is no difference in the informativity and rigidity between independent pronouns (e.g., Hebrew *ani*, 'I') and the corresponding agreement marker (+*ti* for past tense). But distributional patterns show that the independent pronoun (less attenuated) is used when the speaker is less accessible. Finally, for Western names, it's usually the case that first and last names are equally informative and attenuated, but they are not equally rigid. Last names tend to pick a referent more uniquely than first names (simply because there is a greater variety of last names). Accordingly, Ariel (1990: 45) correlates the two types of names with different textual positions, showing that anaphoric first names mostly find their antecedents within the same paragraph, but last names have three times as many cross-paragraph anaphoric relations. This points to the lower degree of accessibility indicated by last names.

Distance between a previous and a current mention of the entity (recency) is indeed one important factor determining degree of accessibility. Naturally, the longer the time elapsed between the previous and the current reference, the less activated the representation, so that relatively lower accessibility markers are called for. Note that the relationship between the antecedent and the anaphor, their Unity, is not simply measured in number of words (only), but rather, syntactic boundaries (e.g., the clause), textual boundaries (the paragraph, the episode), and pragmatic boundaries (units more vs. less cohesively linked to each other) define the closeness between a potential antecedent and its anaphor, dictating higher or lower accessibility markers depending on how 'distant' the two are from each other. When a discourse entity is inferred based on another, we similarly see differences according to how automatic/stereotypic the inference connecting the two is (cf. *her heart* in [2], which is easily inferred from *her*, given that humans have hearts, with *his sense of character values* based on *his* referring to *Mister Forster* – SBC: 023, where we don't automatically assume that people have a "sense of character values"). Empirical evidence for these Unity claims can be found in Clancy (1980), Sanford and Garrod (1981), Givón (1983), and Ariel (1985a and onward).

Unity features mostly pertain to anaphoric references. Referent salience is important for all types of reference, first-mention referential expressions included. Some discourse entities are inherently more salient: the speaker and addressee (vs. third persons), humans (especially vs. inanimates), and famous personalities (vs. anonymous people). Other discourse entities have a prominent *ad hoc* status, mostly because they constitute discourse topics. The predictions are then that higher accessibility markers will serve these more salient discourse entities. Competition over the role of intended referent between potential mental representations may, however, lower the degree of accessibility of each, mainly of nontopics. It then calls for lower accessibility markers:

(4) MARY: What I have to do,
is take off **the distributor wire**$_i$,
and splice **it**$_i$ in with **the fuel pump wire**$_j$.
Because **my** . . . **fuel pump**$_j$ is now electric, (SBC: 007).

(5) In the reference, each author is referred to by name and initials. There is a single exception – to avoid the possibility of confusion, first names are always included for **David Payne**, **Doris Payne**, **John Payne**, **Judith Payne** and **Thomas Payne** (Dixon, 1994: xvi–xvii).

In (4), the more topical entity is coreferred to by *it*, the nontopic by an informative lexical NP (*my fuel pump*). In (5), presumably equally accessible entities are all referred to by lower accessibility markers (full names), because they compete with each other (initial + *Payne* is not rigid enough in this context).

It is important to remember, however, that accessibility theory makes claims about correlations between referring expressions and degree of accessibility, measured as a total concept, rather than by any one of its components (e.g., topic, distance, or competition). In other words, the prediction is that accessibility marker selection is determined by weighing together a whole complex of accessibility factors, which together determine what the degree of accessibility of a given discourse entity is at the current stage of the discourse (see Toole, 1996; Ariel, 1999). This is why, for example, even speakers are not invariably referred to by the highest accessibility markers (zero in Hebrew). Although the speaker is a highly salient discourse entity, if she's not topical or if it's competing with another antecedent, it may be referred to by an independent pronoun.

Finally, accessibility theory is universal (see Ariel, 1990: 4.2), although not all languages have exactly the same set of referring expressions, and even when these seem to be identical, they may rate differently for the three coding principles (informativity, rigidity, and attenuation, e.g., cf. English and Japanese pronouns). Provided they are comparable, all referring expressions are predicted to indicate the same relative, though not absolute, degrees of accessibility. Thus, in all languages zeroes indicate a higher degree of accessibility than pronouns, but not all languages allow cross-sentential zero anaphora. Accessibility theory applies to all genres/registers (see Ariel, in press). In fact, because accessibility related discourse patterns are so common in diverse registers and languages, we can account for various cross-linguistic grammaticization paths. For example, the recurrent creation of verbal person agreement markers for first/second persons, but not for third persons (via the cliticization of the high accessibility markers used for the very salient speaker and addressee; see Ariel, 1998b, 2000), as well as universal constraints on the use of resumptive pronouns (see Ariel, 1999). At the same time, accessibility constraints may be violated to create special pragmatic effects (e.g., *Jamie the old lady* (SBC: 002) is too low an accessibility marker, when used by Jamie's husband in her presence).

Acquired Impairments of Written Language

C Luzzatti, Universita' degli Studi di Milano-Bicocca, Milan, Italy
H A Whitaker, North Michigan University, Marquette, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

An adult individual who acquired normal reading and spelling skills may lose these abilities after cerebral damage. Reading and spelling may be impaired either in isolation after a lesion to the brain areas that are specifically involved in storing or processing orthographic representations, or in accompaniment with aphasia, i.e., in association with more general language disorders.

Phylogenetic Observations

Language is a function that has developed during the natural evolution from the primate to the human species. The phylogenetic and ontogenetic development underlying language acquisition is based on neuroanatomical and functional units that are genetically determined. This assumption is clearly demonstrated for the acquisition of oral language, but the generalization to the functional units specifically devoted to the processing of written language is more difficult to maintain. In fact, the use of written language has emerged much more recently, i.e., not much earlier than 6000 years ago, and – even more crucially – part of the human population is still illiterate or has become literate only during the last few generations. Despite that, every child has the identical capacity of acquiring the ability to read and write, irrespective of the degree of literacy achieved by his/her social and ethnic group.

Writing Systems

Populations from different parts of the world developed different systems for transcribing oral language representations in a sequence of written symbols. Even if such a distinction is clearly too simplistic, the writing systems adopted all around the world may be distinguished along the major dichotomy of ideographic and alphabetic writing systems. In ideographic writing systems, symbols correspond to the meaning of words. In alphabetic writing systems, each symbol (or set of symbols) corresponds to a sound (or set of sounds).

The major advantage of alphabetic systems derives from their regularity and from the possibility of combining few (usually 20–50) symbols in strings of letters. However, it must be kept in mind that, in particular for languages whose orthography has been codified several centuries ago (such as French or English), the correspondence between symbols and sounds (graphemes and phonemes) may not be regular anymore.

The major advantage of ideographic systems (e.g., the Chinese one) derives from the possibility that a unique written code may be shared (i.e., may be understood) by many populations speaking fully different dialects or languages. However, most ideographic writing systems are in fact intermediate systems, where ideograms are mixed with characters

Introduction

An adult individual who acquired normal reading and spelling skills may lose these abilities after cerebral damage. Reading and spelling may be impaired either in isolation after a lesion to the brain areas that are specifically involved in storing or processing orthographic representations, or in accompaniment with aphasia, i.e., in association with more general language disorders.

Phylogenetic Observations

Language is a function that has developed during the natural evolution from the primate to the human species. The phylogenetic and ontogenetic development underlying language acquisition is based on neuroanatomical and functional units that are genetically determined. This assumption is clearly demonstrated for the acquisition of oral language, but the generalization to the functional units specifically devoted to the processing of written language is more difficult to maintain. In fact, the use of written language has emerged much more recently, i.e., not much earlier than 6000 years ago, and – even more crucially – part of the human population is still illiterate or has become literate only during the last few generations. Despite that, every child has the identical capacity of acquiring the ability to read and write, irrespective of the degree of literacy achieved by his/her social and ethnic group.

Writing Systems

Populations from different parts of the world developed different systems for transcribing oral language representations in a sequence of written symbols. Even if such a distinction is clearly too simplistic, the writing systems adopted all around the world may be distinguished along the major dichotomy of ideographic and alphabetic writing systems. In ideographic writing systems, symbols correspond to the meaning of words. In alphabetic writing systems, each symbol (or set of symbols) corresponds to a sound (or set of sounds).

The major advantage of alphabetic systems derives from their regularity and from the possibility of combining few (usually 20–50) symbols in strings of letters. However, it must be kept in mind that, in particular for languages whose orthography has been codified several centuries ago (such as French or English), the correspondence between symbols and sounds (graphemes and phonemes) may not be regular anymore.

The major advantage of ideographic systems (e.g., the Chinese one) derives from the possibility that a unique written code may be shared (i.e., may be understood) by many populations speaking fully different dialects or languages. However, most ideographic writing systems are in fact intermediate systems, where ideograms are mixed with characters

or parts of characters bearing morphological and/or phonological information.

Reading and Spelling Impairments in Classical Aphasiology

The first model of reading and spelling and of the cerebral implementation of written language was developed by Carl Wernicke (1874) based on the reading and spelling deficits observed in aphasic patients.

A few years later (1883), Charcot developed his famous anatomofunctional model in which he represented oral and written input and output modalities as symmetric and independent processing units (Figure 1).

A symmetric independent organization of written language with respect to oral language was rejected by Lichtheim (1885), who proposed a dependent asymmetric model (see Figure 2) in which a reading (O) and a spelling center (E) both depend upon a center of auditory images of words (A). In a later study, Wernicke (1885–1886) partly accepted Lichtheim's diagram, but suggested a reanalysis of the operations underlying the processing of written language: he first excluded a symmetrical organization with respect to oral language, but he also refuted the notion of a complete subordination of written to oral language. In his final model, he opposed a diagram of written language in which letters are the atomic processing units to a model of oral language in which words are the atomic units (*wir sprechen nicht buchstabierend*, 'we do not speak letter-by-letter [in fact sound-by-sound]'). To support his hypothesis, he introduced an abstract unit (gamma), which is neither sensory nor motor, but allows the mapping of oral lexical units to the corresponding letter strings and the mapping of letter strings to the corresponding (oral) words (for an extensive discussion of Wernicke's [1885–1886] thought, see De Bleser and Luzzatti, 1989). (It must be underlined that at that time, the linguistic theory did not conceive yet of a segmentation of words into further abstract units of representation, i.e., the phonemes.)

Figure 1 Charcot's diagram (1883). The sound of a bell is identified through the common auditory center (CAC); the spoken word *bell* is identified through the center of auditory memory of words (CAM); the image of a bell is identified through the common visual center (CVC); the written word *bell* is identified through the center of visual memory of words (CVM); the word *bell* is pronounced through the center of articulatory movements (CPM); the word *bell* is written through the center of graphic movements (CGM); the concept of a bell is stored in the ideatory center (IC).

Pure Forms of Reading and Writing Disorders

On the basis of clinical descriptions and later autopsy of two patients suffering from isolated impairment of written language, Déjerine (1891, 1892) developed an anatomofunctional model of reading and spelling that remained unchallenged until the second half of the 20th century. In the first patient, suffering from a reading and spelling disorder in absence of any deficit of oral language (alexia with agraphia), the lesion causing the impairment was confined to the left angular gyrus. The second patient suffered from right hemianopia and complete alexia with the exception of single digits (pure alexia, i.e., alexia without agraphia); the lesion in this case involved the left occipital lobe, extending to the splenium of the corpus callosum.

On the basis of his clinical observations, Déjerine developed an anatomical model of written language. In his diagram (see Figure 3) the angular gyrus is considered to be the store of all acquired orthographic representations (using his terminology,

Figure 2 Lichtheim's (1885) model of oral and written language. Left, oral language. Right, oral + written language: dependent asymmetric model in which a reading (O) and a spelling center (E) depend both on the center of auditory images of words (A).

Figure 3 Déjerine's anatomical model of written language. CVM: center of visual memories; OVC: occipital visual center; CAM: center of auditory memories (i.e., the Wernicke's area); MCA: motor center of word articulation (i.e., Broca's area); HMC: hand motor center. Alexia with agraphia would be caused by a damage to CVM, while pure alexia by damage to the left OVC and isolation of CVM from the controlateral right OVC.

the center of visual memories, CVM). The visual images of letters and words are perceived either in the left or the right occipital visual center (OVC) and projected to CVM for identification and further on to the center of auditory memories (CAM, i.e., Wernicke's area) for lexical (and semantic) access. Letter and word naming would require the further connection to the motor center of word articulation (MCA, i.e., Broca's area). On the contrary, written spelling would flow from CAM to CVM and further on to the hand motor center (HMC) where the graphic motor patterns of letters are stored.

Following Déjerine functional-anatomical model, alexia with agraphia would be caused by a damage to the CVM, while pure alexia by damage to the left OVC and isolation of CVM from the contralateral right OVC, due to the splenial lesion of the corpus callosum.

Cognitive Models of Reading

Déjerine's anatomical and functional model remained for many decades the standard reference for the analysis and explanation of reading and writing impairments. However, the qualitative analysis of the reading performance of some aphasic patients (Marshall and Newcombe, 1966, 1973) pointed out that none of the classical models could account for several of the phenomena, such as the emergence of semantic substitutions, grammatical class effects

Figure 4 Dual-route model of reading. Lexical and subword-level routes of reading.

(better performance on nouns than on function words), imageability effects (better performance on concrete words), and word frequency effects (better performance on higher frequency words). Furthermore, the classical models did not consider some aspects of reading performance such as selective damage of irregular words or the inability of some patients to read regular nonwords (possible but nonlexical orthographic strings). These observations were consistent with the model of reading (the logogen model) developed in this period by Morton (1969, 1980).

Dual Route Models of Reading

The ability a normal subject has to read regular nonlexical strings as well as words with irregular or unpredictable orthography (e.g., *yacht*, *pint*, or the ambiguous pronunciation of the letter string EA in *dear*, *bear*, *heart*, or *steak*) suggest two complementary reading procedures, a subword level and a lexical level (Figure 4).

The subword-level procedure allows the conversion of a string of graphemes into their corresponding phonemic string. The route is based on basic sublexical orthographic-to-phonological conversion rules, and accounts for reading regular words (i.e., words with fully predictable pronunciation such as *dog* or *cake*) and nonlexical but possible orthographic strings (nonwords), such as *balt* or *mable*.

The lexical procedure assumes the existence of two lexical stores listing the orthographic and phonological representations of words whose orthography and/or phonology have already been learned by an individual. Naming a written word requires the activation of its orthographic form in an orthographic input lexicon. This lexical unit activates the underlying conceptual knowledge and later on the corresponding phonological representation from a lexical mental store (the phonological output lexicon).

The lexical route is quicker than the subword-level procedure and automatically activates word meaning, but can be used only for words whose orthography is already known by a subject, and not for nonlexical orthographic strings, and is finally the only possible route to read words with irregular or unpredictable orthography.

The phonemic string generated along either reading route is further conveyed to the phonemic buffer, a short-term store interfacing the phononogical representations with those devoted to the articulatory planning.

Lexical Analogy Models

In English, words containing letter strings with ambiguous pronunciation (*veal*, *deaf*, *steak*) are named more slowly than words with no ambiguity (Glusko, 1979). This difference has been explained as an interaction of subword-level procedures even when reading highly frequent words, and indicates that both word and nonwords are read accessing the phonological lexical representations of known words. Words stored in the orthographic lexicon would be linked for orthographic similarity. A written string (word or nonword) would activate all linked lexical strings. This would allow, by analogy, pronunciation of nonwords.

Reading Impairments in a Cognitive Neuropsychological Frame

The dual route information processing model described so far predicts the possible impairment of either reading route, namely selective damage to either the subword level, or the lexical reading procedure. In fact, some patients suffering from acquired language impairments show exactly the predicted pattern of damage.

Figure 5 Dual-route model of reading. Functional lesions causing phonological and surface dyslexia.

Table 1 Principal patterns of damage characterizing phonological and surface dyslexia[a]

	Phonological dyslexia	*Surface dyslexia*
Regular words	+	+
Irregular words	+	−(→regular)
Nonwords	−	+
Lexical effects (WF, Gram. class, Concr.)	yes	no
Length effect	no	yes

[a]The symbol + indicates no or mild disorder, the symbol − indicates more severe disorder. WF = word frequency; Gram. class = grammatical class; Concr. = concreteness; → regular = regularization of irregular words.

Phonological or Surface Dyslexia

Damage to the grapheme-to-phoneme conversion rules is usually called phonological dyslexia, while damage to the lexical route goes under the label of surface dyslexia (Figure 5). Table 1 summarizes the principal aspects of these two major types of reading impairment.

Direct Dyslexia

The observation of patients who could read irregular words but not understand them (e.g., the case W. L. P. of Schwartz *et al.*, 1980) suggested a direct connection of the orthographic input lexicon to the phonological output lexicon, by-passing the underlying conceptual knowledge.

Deep Dyslexia

As already mentioned, some patients make semantic reading errors (e.g., they read *dog* instead of *hound* or *tree* instead of *wood*). Semantic paralexia is a phenomenon observed in some cases presenting with the pattern of errors similar to that described for phonological dyslexia (selective damage to the subword-level reading route); this reading impairment may be associated with grammatical class effects (nouns are read better than verbs or function words) and imageability effects (concrete words are read better than abstract words). Together, this peculiar type of reading disorder is called deep dyslexia. It often characterizes the reading performance of severe agrammatic patients. One explanation for this is the emergence of

right hemisphere linguistic abilities after extensive damage to the left hemisphere language areas (Coltheart, 1980, 2000).

Letter-by-Letter Reading

This type of reading impairment usually appears in isolation from other language disorders and corresponds to the classical concept of pure alexia (Déjerine, 1892). Patients are unable to name a target word either through the lexical or the subword-level route. However, they may still be able to name the letters of words, but the procedure is typically slow and often ineffective. There is a strong word length effect, but no word frequency or word class effect (Patterson and Kay, 1982; Kinsbourne and Warrington, 1962; Coslett and Saffran, 1989).

Neglect Dyslexia

Another type of reading impairment arises in association with visuospatial neglect, due to a hemi-inattention and/or a left side representational impairment of the visual field, body, and extrapersonal space. In a word-naming task, patients neglect the left side of words. Reading errors may be either omissions (e.g., *race* for ***terrace***) or substitutions (e.g., *window* for ***meadow***). When reading a string of words, patients usually start from the middle of the string, leaving out the left side of it; they are often unaware of their impairment (anosognosia).

Diagnosis of Reading Impairments

To analyze the nature of an acquired reading impairment, three major tasks should be used: lexical decision, semantic judgment, and reading aloud. In a lexical decision task patients are asked to decide whether strings of letters are real words or nonwords. In a semantic judgment task, patients are asked to make decisions about the meaning of words they may not be able to read (e.g., whether a certain word refers to an edible or nonedible item). According to contemporary reading models, a reading task should include words with both regular and irregular letter-to-sound correspondence and nonwords. The second set of stimuli should only be read along the lexical route, the third along the grapheme-to-phoneme conversion route, while the first set may be read along both routes. Lists of words should also vary by grammatical class, word length, word frequency, and morphological complexity (cf. the PALPA test by Kay *et al.*, 1992). The National Adult Reading Test (NART; see Nelson, 1982) assesses the ability to read words with irregular letter-to-sound correspondence. It has been standardized on a large sample of English-speaking normal adults. As expected, the NART score correlates highly with the education level.

Clinical Neuropsychological Classification of the Spelling Impairments

During the first half of the 20th century, clinical neuropsychologists distinguished six types of spelling disorders: aphasic agraphia, alexia with agraphia (see Déjerine's model of written language), pure agraphia, apraxic agraphia, callosal agraphia, and visuospatial agraphia.

Aphasic Agraphia

The spelling impairment mirrors the clinical aspects of the oral language impairment. In addition to the deficit that arises from the right hand motor impairment that often co-occur with language dysfunction, most aphasic patients suffer from a widespread writing disorder with letter omissions, substitutions, perseverations, and spontaneous repairs. Severe fluent language impairments often assume the characteristics of a jargon agraphic output (neologisms), while nonfluent language impairments are often in association with a deficit in realizing the orthographic strokes of letters.

Alexia with Agraphia

See 'Pure forms of reading and writing disorders.'

Pure Agraphia

This is the type of spelling impairment predicted and described by Charcot (1883) in his early model under the label of motor aphasia of the hand. It is a damage to orthographic representations and therefore involves handwriting as well as oral spelling or writing on a keyboard. It has been described for left parietal and in some rare cases for left frontal lesions.

Apraxic Agraphia

In this type of writing impairment oral spelling and typing on a keyboard are spared. The inability to realize letter symbols may follow either a failure to retrieve letter forms from memory or to a difficulty in realizing these forms graphically and combining individual letter strokes appropriately. The disorder cannot be traced back to an ideomotor or constructional apraxic deficit, since both types of apraxia may not involve writing abilities and, vice versa, apraxic agraphia may emerge without any major apraxic deficit.

Callosal Agraphia

This type of impairment is usually caused by anteromedial damage to the corpus callosum. Agraphia appears in this case for the left hand only (due to a

disconnection from left-hemisphere writing centers). It is often associated with left-hand apraxia and left-hand tactile anomia.

Visuospatial (Neglect) Agraphia

By analogy to neglect dyslexia (see above), there is also a spelling disorder that may arise in association with left spatial neglect. Patients may produce writing and spelling errors that only involve the left side of words. This phenomenon was interpreted as a left-side neglect of mental orthographic representations (Baxter and Warrington, 1983).

Cognitive Models of Spelling

In analogy to the dual route models of reading, cognitive psychologists have also developed dual route models to describe the spelling performance of normal adult subjects. These models assume two independent procedures, a lexical route along which words are processed as a whole, and a subword-level routine based on phoneme-to-grapheme conversion rules (see Figures 6 and 7). A dual-route model offers the best account so far for the ability of a literate subject to spell both irregular words and legal nonwords. Once again, the major evidence for a dual-route model of spelling derives from the observation of aphasic patients suffering from acquired spelling disorders (Beauvois and Dérouesné, 1981; Shallice, 1981; Baxter and Warrington, 1985; Harris and Coltheart, 1986; Patterson, 1986).

As with the lexical route of word naming, the lexical route of writing (to dictation) implies two stores listing the phonological and orthographic lexical knowledge of a subject and another lexical semantic store. After auditory analysis, input words activate phonological lexical knowledge stored in the phonological input lexicon. Stored lexical knowledge spreads activation to the underlying conceptual knowledge, which in turns activates the orthographic output knowledge stored in the orthographic output lexicon.

This procedure allows one to spell regular and irregular words whose orthography had already been learned, but cannot be used when spelling new words or nonwords; it is the only procedure available for spelling irregular words.

Sub-word-level procedures permit one to convert a string of sounds into its corresponding orthographic string, following phoneme-to-grapheme conversion rules. This procedure allows one to spell regular words and nonlexical phonemic strings (nonwords).

The routine can be divided in several sequential components: after auditory analysis, the continuous flow of sounds has to be segmented and further translated into the underlying phonemic string

Figure 6 Dual-route model of spelling. Lexical and subword-level routes of spelling.

Figure 7 Dual-route model of spelling. Functional lesions causing phonological and surface dysgraphia.

(auditory-to-phonological conversion); the string is then reassembled in the phonemic buffer, and then conveyed to sequential translation by the phoneme-to-grapheme conversion rules into its appropriate graphemic string.

Both spelling procedures feed the graphemic buffer, a short-term memory store controlling the temporal sequencing of the selected graphemic string, and interfacing the abstract orthographic units with more peripheral processing units underlying different output modalities (handwriting, writing on a keyboard, and oral spelling).

Spelling Impairments in a Cognitive Neuropsychological Frame

The spelling disorder an adult subject may acquire after focal brain damage is caused by an impairment of the lexical and/or the subword-level spelling route.

Damage to phoneme-to-grapheme conversion procedures causes a spelling impairment that is usually called phonological dysgraphia. The alternate pattern of impairment is called surface dysgraphia and follows damage to the lexical route of spelling. Table 2 summarizes the contrasting phenomena characterizing these two types of dysgraphia.

Deep Dysgraphia

By analogy to reading impairments, there is a subtype of phonological dysgraphia called deep dysgraphia, which is characterized by the emergence of semantic errors. The spelling impairment in deep dysgraphia is usually associated with grammatical class (nouns are spelled better than verbs or function words) and imageability effects (concrete words are spelled better than abstract words).

Graphemic Buffer Disorders

This is a spelling disorder in which graphemic substitutions predominate. However, with respect to the previous types of dysgraphia, in graphemic buffer dysgraphia the orthosyllabic structure of the stimulus is preserved (vowels are substituted to other vowels, consonants are substituted by consonants, and the structure of clusters and doubled consonants is preserved). A comparable impairment emerges both for words and nonwords. This set of phenomena suggests that substitutions arise at an advanced stage of the spelling processes, i.e., in a phase where the orthosyllabic structure of the stimulus to be spelled has already been formed.

Table 2 Principal patterns of damage characterizing phonological and surface dysgraphia[a]

	Phonological dysgraphia	*Surface dysgraphia*
Regular words	+	+
Irregular words	+	−(→regular)
Nonwords		+
Lexical effects (WF, Gram. class., Concret.)	yes	no
Length effects	no	yes

[a] The symbol + indicates no or mild damage, the symbol − more severe impairment. WF = word frequency; Gram. class = grammatical class; Concr. = concreteness; → regular = regularization of irregular words.

Peripheral Dysgraphia (Allographic Dysgraphia)

This is a set of writing impairments originating at a peripheral stage with respect to the graphemic output buffer. It usually involves handwriting, leaving oral spelling and the ability to write on a keyboard unimpaired. Some patients are unable to distinguish lower- and upper-case letters, mixing these two sets of characters during handwriting.

This impairment must be distinguished from apraxic dysgraphia (see above), because the output observed in allographic dysgraphia may be fluent and letter shapes are typically well formed.

Diagnosis of Spelling Impairments

In analogy to reading tasks, writing tasks should contain several sets of items, i.e., words with regular spelling, words with irregular spelling, and nonwords. Words should vary for grammatical class, word length, word frequency and morphological complexity. Finally, patients should be tested for oral and written spelling, copying, delayed copying, and repetition. Cognitive neuropsychologists studying patients for their writing disabilities usually devise their own lists of items designed specifically to test certain aspects of the patient under study.

Spelling abilities may be assessed in English-speaking subjects using the PALPA test (Kay *et al.*, 1992). The test includes writing and spelling of regular and irregular words (from different grammatical classes and of variable length and frequency), writing and spelling of nonwords, and written naming of object pictures.

Actantial Theory

P Perron, University of Toronto, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

The term 'actant' was borrowed from the French linguist Lucien Tesnière by the semiotician Algirdas Julien Greimas (1917–1992), founder of the Paris School of semiotics who held a yearly research seminar for more than 30 years that is still active today (Coquet, 1982). Tesnière (1969: 102) defined actants as "beings or things that participate in processes in any form and in anyway whatsoever, be it only a walk-on part and in the most passive way." For him, the verbal nucleus of a sentence represented a sort of minor drama in the theatrical sense or a process expressed by the verb and whose dependents are substantives (actants that can be defined as that which undertake or undergo an act) and adverbs (circumstances of time, place, goal, cause, etc. in which the action unravels). At the structural syntactical level, actants designate the characters in the drama, the verb designates the process, and the circumstants designate the situation. The actant therefore designates a type of syntactic unit that is formal in character but in a distinct relationship to the predicate and the circumstants. Whereas the number of circumstants can vary greatly, there can only be three actants: the subject, the object of an active verb or the agent of a passive verb, and the beneficiary.

However, Greimas's definition of the term actant departed from Tesnière's and evolved over the course

Actantial Theory

P Perron, University of Toronto, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

The term 'actant' was borrowed from the French linguist Lucien Tesnière by the semiotician Algirdas Julien Greimas (1917–1992), founder of the Paris School of semiotics who held a yearly research seminar for more than 30 years that is still active today (Coquet, 1982). Tesnière (1969: 102) defined actants as "beings or things that participate in processes in any form and in anyway whatsoever, be it only a walk-on part and in the most passive way." For him, the verbal nucleus of a sentence represented a sort of minor drama in the theatrical sense or a process expressed by the verb and whose dependents are substantives (actants that can be defined as that which undertake or undergo an act) and adverbs (circumstances of time, place, goal, cause, etc. in which the action unravels). At the structural syntactical level, actants designate the characters in the drama, the verb designates the process, and the circumstants designate the situation. The actant therefore designates a type of syntactic unit that is formal in character but in a distinct relationship to the predicate and the circumstants. Whereas the number of circumstants can vary greatly, there can only be three actants: the subject, the object of an active verb or the agent of a passive verb, and the beneficiary.

However, Greimas's definition of the term actant departed from Tesnière's and evolved over the course

of the years. It was initially worked out in *Structural semantics* (1983) and must be situated within the general economy of his semiotic theory. Following the Danish linguist Louis Hjelmslev, Greimas stated that semiotic theory must be submitted to the principle of empiricism, which demands that it fulfill three hierarchically organized conditions: the condition of coherence (or of noncontradiction), the condition of exhaustibility, and the condition of simplicity.

Greimas's point of departure, which owes a great deal to Claude Lévi-Strauss and Roman Jakobson with respect to its methodological and theoretical underpinnings, was that the investigation of meaning is by definition a metalinguistic activity that paraphrases and translates words and utterances by means of other words and utterances. For him, the first step in describing signification resided in the transposition of one level of language into another level, of one language into another language. Since meaning could be described as this very possibility of transcoding, it was necessary to develop a new terminology and construct an adequate metalanguage that could account for the object in question. Thus, to uncover the 'mythological signified,' Greimas (1987: 3–16) endeavored to work out a rigorous methodology based on objective criteria of analysis partially adopted from structural linguistics, which had, at the time, more or less abandoned research in the area of semantics. Much in the same way that Lévi-Strauss overanalyzed the Oedipus myth, Greimas began by 'overanalyzing' Georges Dumézil's work on myth, considered as the translation of mythological language into ideological language. In short, he proposed a new formulation of Dumézil's analysis using the study of myth and the structural methodology borrowed from the social sciences to examine the superstructures of social ideologies. This constituted a major development from a semiotic point of view since in Hjelmslev's terms a 'connotative semiotics' was transformed into a 'denotative semiotics' that, for him, was a precondition for an adequate description of a text.

By reducing the problem of meaning to its minimal dimensions (i.e., to the transcoding of significations), 'scientific' activity in this domain consisted of establishing techniques of transposition. (For definitions and interdefinitions of terms, see Greimas and Courtés, 1982, 1986). The main feature in the analysis of Dumézil's work can be found in the conversion of the syntagmatic manifestation of myth into paradigmatic relations or, in other words, in the setting up of correlations between a limited number of units of the mythic signified distributed throughout the narrative. A relevant level was defined and a discourse, based on the principle of interdefinition, was constructed on the mythological object as a first important methodological step. However, this new formulation of Dumézil's text does not correspond *stricto sensu* to formalization, as defined, for example, by logicians in formal theory. From the outset, semiotics was not considered a formal language as such but, rather, an intermediary stage toward explanation – toward giving a more scientific account of meaning.

The conclusions of this study clearly pointed to the insufficiencies of Lévi-Strauss's paradigmatic definition of myth, despite the real gains made in adopting the preceding methodological perspective. The structural anthropologist considered the myth as a correlation of two pairs of units of the signified that are in significant opposition to each other and that exclude any syntagmatic relations. Greimas did use methodological procedures borrowed from structural anthropology and even refined major constituent units by breaking them down into distinctive features called semes that he defined as the minimal units of signification. Located at the level of content, a seme corresponds to the pheme, the unit at the level of expression. Hypothetically, a semantic system can account for the level of content of a semiotic system that is comparable to the phonological system at the level of expression or semic categories and archilexemes (sets of semic categories constituting pairs of lexemic oppositions making up the elementary structures of myth). However, he also made a case for the need to investigate syntagmatic structures that could be grounded in discourse analysis in addition to the Lévi-Straussian paradigmatic structures.

Greimas presented a syntactic and semantic (actantial) theory of discourse for the first time in *Structural semantics* (1983) (see Jameson (1972, 1987) and Schleifer's introduction to *Structural semantics* (Greimas, 1983) for a detailed account of the theoretical underpinnings of the first stages of the actantial model). In this essay, Greimas elaborated the elementary structure of signification, the notion of semantic axes and that of semic articulation, and defined semes in relationship to lexemes, along with the notion of isotopy that designates both the repetition of classemes and the recurrence of semic categories, be they thematic, abstract, or figurative. He established the categories of predicate and actant, logical syntax, and semantics in the description of signification while stressing the modal character of the actantial categories. He worked out the actantial model – composed of a Sender and a Receiver, a Subject and an Object, aided or hindered by a Helper or an Opponent – and gave a detailed example of the description, focusing on the semantic universe of the French 20th-century novelist, Georges Bernanos.

The investigation of the gestural domain of the natural world, through the description of relevant features at the level of content that are at the same time distinctive and significant, brings to the fore the anthropological dimension of Greimas's actantial theory at the core of his narrative semiotics. In his first major study (1987: 3–16), Greimas focused on the paradigmatic organization of text. On the contrary, in a second important study (1987: 19–47) he investigated the syntagmatic dimension of gesture, considered both as a 'discursive structure,' because it appears within the context of the subject/object relation, and as an 'utterance' constructed by the human subject and deciphered by another subject, within the context of a program of enunciation that is at the very origins of intersubjective relations. He examined the semiotic status of gestural signs, which were defined in terms of the semiotic relation between expression and content, in conjunction with the fundamental problem of identifying what actually constitutes gestural units. He viewed human beings as bodies but also as figures of the world and then as complex mechanisms that, through mobility, produce differential (positional) gaps at the level of the signifier by which signification can take place at the level of the signified. He explored gestural activity within the framework of the project defining it. Consequently, a programmed gestural project constituted the signified of gestural activity, whereas the gestural sequence was equated with its signifier. In this way, he was able to define the semiosis of a gestural program as the relation between a sequence of gestural figures taken as the signifier and the gesture project considered as the signified. However, the analysis of gestuality did raise problems regarding the functional nature of gestural semiotics.

One of the major obstacles that needed to be overcome in the general semiotic theory of the 1960s and 1970s was to free it from the theoretical constraints of structural linguistics. André Martinet (1960) proposed as general hypothesis that all languages were organized according the principle of the 'double articulation.' On the first articulation or first level, the utterance is articulated linearly by means of units having meaning (sentences, syntagma, words, etc.), the smallest of which he called morphemes: The sentence *The baby will sleep* is articulated by means of four morphemes (The [1] baby [2] will [3] sleep [4]), each of which can be replaced in a different environment by other morphemes on the paradigmatic axis or can end up in a different environment combined with other morphemes on the syntagmatic axis.

At the second articulation, or second level, each morpheme is articulated in turn at the level of the signifier by means of units having no meaning (distinctive units), the smallest of which are phonemes that are limited in number in every language. Hence, the morpheme sleep (sli:p) is made up of four phonemes, each of which can be replaced by another in the same environment or combined with others to form a different morpheme. The signified can also be broken down, but not linearly, into units of meanings or semes: *baby* = [human] + [very young]. Within this theoretical environment, Greimas identified the need to work out a level of analysis dealing specifically with the organization of content that would be part of a general functional semiotics also encompassing the semantic dimension of natural languages. He also hinted at the possible form it could take. The problem with the structural analysis of gesture is that there are no such things as gestemes or a small number of minimal units of gesture that can be combined to make up morphemes that inform all the gestural systems in all cultures.

Yet the cornerstone of Greimas's actantial theory and narrative semiotics was laid out in the study 'The interaction of semiotic constraints' (1987: 48–62), co-authored with François Rastier, and in 'Elements of a narrative grammar' (1987: 63–83). These two works openly acknowledged a debt both to Vladimir Propp (1968), who provided the syntactic component for the deep semionarrative grammar, and to Lévi-Strauss (1963), who furnished the idea of the semantic component. Greimas redefined Propp's 31 functions (designating syntagmatic units that remain constant despite the diversity of narratives, and whose ordered sequence makes up the structure of folktale) in terms of a limited number of actants. This made it possible to conceive of a principle of organization underlying whole classes of narratives. Thus, deep structures were defined as being the principle of organization not only of figurative discourses but also of abstract discourses (philosophical, political, scientific, etc.), as well as of other semiotic systems not necessarily expressed through natural languages (cinema, figurative painting, architecture, advertising, gesture, etc.). Moreover, following Jean Petitot-Cocorda (1985), I suggest that these structures are lived existentially in human passions, ideology, actions, and dreams, and that actantial and semionarrative structures, to borrow a phrase from Gilbert Durand (1963), can be thought of as 'the anthropological structures of the imaginary.' The goal then for Greimas was to work out a means, or a grammar, that could account for such structures. Indeed, the actantial and semionarrative grammar he elaborated established a specific relation between syntax and semantics, which Petitot-Concorda (1985: 48–49) described as the projection of the paradigmatic axis onto the syntagmatic axis, the understanding of which for him constituted

one of the central problems of structuralism, perhaps even its most central one.

Greimas then had to postulate the existence of a semantic universe that was defined as the set of the systems of values that can be apprehended as meaningful only if it is articulated or narrativized. Thus, any discourse was said to presuppose a semantic universe hypothetically made up of the totality of significations, postulated as such prior to its articulation, and which it actualizes in part. This he called a microsemantic universe that at the fundamental level articulates elementary axiological structures, such as life/death (individual universe) and nature/culture (collective universe). Situated at the deep semantic level, these basic structures were considered to be ad hoc universals that serve as starting points for the analysis of semantic universes, be they individual or collective. Their meaning is never apprehensible as such but, rather, only when they are manifested in the form of an articulated signification or, in other words, when they are converted into actantial structures. Petitot-Cocorda (1985: 50–51) clearly perceived the theoretical import of Greimas's semiotics when he situated the actantial and semionarrative structures within an anthropological framework. For him, the deep semantic categories were considered to be universals of the imaginary even though individuals were thought not to be conscious of them, as they exist only because they are both invested with values and ideologically invested in objects of value, whose quest governs the actions (actantial and narrative programs) of the subject actants. The deep semantic categories can be apprehended only through the circulation of object-values governed by actantial syntax. They cannot be subjectivized in themselves but only by means of a logic of actions. He noted that the role of actantial syntax is to convert the fundamental semantics that constitute the message into narrative and to determine its anthropological function. Finally, it is through this actantial and semionarrative syntax that one can grasp, through the simulacrum of the 'scene' that dramatizes them, the unconscious processes leading to subjectivity.

In 'The interaction of semiotic constraints' (Greimas and Rastier, 1987), Greimas suggested the possibility of a generative trajectory, beginning with a fundamental semiotic level that was then converted into an actantial syntax before ultimately being manifested through discourse, but focused especially on the first domain of the global trajectory. The main object of the theory of the semiotic square at the fundamental semiotic level was to articulate the substance of the content and thereby constitute the form of content. This elementary structure should be considered both as a concept uniting the minimal conditions for the apprehension and/or the production of signification and as a model containing the minimal definition of any language (or, more generally, of any semiotic system or process) and of any semiotic unit. The elementary structure appeared as a complex binary semic category that correlates two contrary semes by means of a relation of junction (conjunction/disjunction) and by a relation of reciprocal presupposition, prior to any semantic investment whatsoever. Petitot-Cocordat (1985: 51–52) argued that the constituent relations of contrariety and contradiction of the semiotic square

> are not logical in nature, but in the Jakobsonian sense are qualitative oppositions and privative oppositions and must be treated as such. The formal characteristics of the semiotic square are founded on a dynamic topology of places and connections and not upon a static logic of terms and connections.

Represented graphically in their entirety, the various components and the interrelationships of the first two levels of the theory of narrativity were worked out in Greimas (1987: 63–83). The semionarrative structures, constituting the most abstract level or starting point of the generative trajectory, are present in the form of a semiotic and narrative grammar. These grammars contain two components (syntactic and semantic) and two levels of depth – a fundamental semantics and a fundamental syntax on the deep level, and a narrative semantics and a narrative syntax on the surface level. Finally, less deep than the other two, the discursive structures take up the surface semiotic structures and set them into discourse. A discursive syntax was identified at this level composed of the subcomponents of actorialization, temporalization, and spatialization. The semantic component, or discursive semantics, was said to be made up of the subcomponents of themantization and figurativization.

The main theoretical problem that arose from this actantial and semionarrative model is related to the passage (conversion), on the one hand, from a paradigmatic relation, or a taxonomic morphology, to an operative syntax or syntagmatic relation and, on the other hand, the passage (conversion) from a fundamental abstract syntax to a narrative anthropomorphic surface syntax and ultimately to a discursive–figurative syntax. It can be said that two types of conversions exist in the theory: 'horizontal' conversions (dealing with the relations between the syntactic and semantic components of each level) and 'vertical' conversions (having to do with the relations between levels). At the deep level, the passage from the elementary morphology constituted by fundamental relations to an operative syntax, or horizontal

conversion, is ensured by the introduction of an actant subject. Equivalencies are established between the fundamental constituent relations of the taxonomic model and the projections of the same relations or operations by means of a horizontal anthropomorphic conversion at the deep level. The relation of contradiction at the taxonomic level as a contradictory operation at the syntactic level negates one of the terms and at the same time affirms its contradictory term.

The problem of vertical conversion, or the passage from the fundamental syntax to the surface anthropomorphic narrative syntax, in this transpositional model was resolved by establishing procedures that set up equivalencies between these two levels. Yet, the equivalencies posited here do not correspond to identity but, rather, are founded on the presupposition that "two or more syntactic forms (or two or more semantic formulations) can be referred to a constant topic" (Greimas and Courtés, 1982: 62). Moreover, insofar as meaning is transformed into signification when articulated, each new articulation can be considered as an enrichment or increase in meaning. Hence, in proceeding from the deep level to the surface levels, the surface must be considered as richer than the deep level and therefore any conversion must be viewed as equivalence and as a surplus of signification. As Greimas stated in an interview with Ruprecht (1984: 14), conversion is homotopic and heteromorphic:

> The forms pass from the deep structures (where operations take place on the semiotic square) to the semionarrative level (where there exists a surface narrative grammar). Both of these levels are concerned with the same thing but in a different way.

The conversion of the deep level into the surface level is ensured by the establishment of equivalencies between syntactic operations at the fundamental level and those occurring at the surface level. Thus, syntactic activity, having been converted from syntactic operation that was itself converted from taxic relations, provides the necessary mediation for the generation of a narrative utterance that is the major component of narrative grammar. The utterance NU = F(A) is seen as a process that is composed of a function, in the Proppian sense, and an actant. Conversion thus rests on the equivalence between the syntactic operation and syntactic activity, on the one hand, and between syntactic activity and an elementary utterance of actantial activity, on the other hand.

Greimas always claimed, and rightly so, that semiotics was not a science but, rather, a scientific project, still incomplete, and that what he was attempting to do was to establish theoretical principles that needed to be completed and transformed. However, we should not minimize the import of the theoretical problems related to the issue of conversion that was already alluded to previously. These are due to the generative conceptualization of the model, according to which various components are linked together along a trajectory that proceeds from the simplest to the most complex, from the most abstract to the most concrete. The problem of conversion and equivalencies is raised on numerous occasions by Greimas. In an interview with Fredéric Nef (1976: 24), Greimas admits,

> A theoretical construct, no matter how satisfying it appears at first view, runs the risk of remaining hypothetical as long as the problem of equivalencies between different levels of depth is not clearly formulated, as long as the procedures of conversion from one level to another have not been worked out.

In a special issue of *Le Bulletin* devoted to the semiotic square, Greimas (1981: 45–46) again stated that one of the urgent tasks facing semioticians was to undertake research on conversion. It is necessary to conceive of and construct procedures for passing from the deep level of semantic categorizations to the more surface ones of anthropomorphic narrative syntax and of its investments. The same awareness of the possible weak point in the theory was demonstrated in Greimas and Courtés (1982: 62) when they stated that the elaboration of conversion rules will constitute one of the fundamental tests of the coherence of semiotic theory.

It is especially on the issue of conversion and equivalencies within the framework of the narrative grammar just sketched that Paul Ricoeur (1989) voiced reservations about the actual coherence of the theory. Ricoeur took issue with the model on three counts. The first concerned the conversion of contradiction at the deep level into polemic at the surface level; that is, polemical negativity cannot be derived either from the taxonomic relations of contradiction–contrariety or from the syntactic operation of negation. The second was related to the fact that there exist syntagmatic supplements at the surface level that cannot be obtained from the conversion of the fundamental grammar to the surface grammar. The third was that the praxic–pathic dimension of narrative established a semantics of action that activates a syntax that is both phenomenological and linguistic. In his work on the morphogenesis of meaning, Petitot-Cocorda (1985) argued that for Ricoeur's critique to be truly pertinent, the implicit phenomenology of the praxic–pathic semantics of action would have to be formalized so that it could be integrated into a formal model. He concluded that the hypothesis of a syntagmatic

supplement that is irreducible to the paradigmatic is tenable only if one forced Greimas's thought and viewed conversion as a simple equivalence between metalanguages, but this was far from being the case (Petitot-Cocorda, 1985: 268). In the final analysis, the real problem in the theory that must be addressed is the one Greimas raised all along, namely the need to establish the actual procedures of conversion.

The anthropomorphic actantial dimension mentioned previously establishes relations between subjects and objects, subjects and antisubjects, and subjects and senders and receivers. The first relation, which is founded on the establishment of the subject as a wanting subject and of the object as an object of value, was described in terms of modal utterances. Wanting is the first of a series of determined semantic restrictions that specify actants as virtual operators of an act; the second restriction is having. Other semantic restrictions, the introduction of the modalities of being-able and knowing, constitute the being or the activity of the actant subject. The relation of subject and object was formulated syntactically in terms of utterances of state that are conjunctive or disjunctive in nature. The second relation between subject and antisubject was considered as the conversion of the paradigmatic relation.

The third relation between subject and sender, subject and receiver was reformulated in terms of a general structure of exchange. The attribution of an object of value was defined as a disjunctive operation (privation) and a conjunctive one (attribution). This reformulation made it possible to represent the previous operations as places of transfers of objects of value from one location to another. A topological syntax of objective values was established that, since it follows the logical operations at the level of deep grammar, organizes narration as a process creating values. However, by changing focus and examining the relations between operators – subject and sender or receiver – we can see that topological syntax governs the transfer both of the subject's capacity to do and of the values. Also, the topological syntax governs the institution of syntactic operators by subjects with the virtuality of doing. In a later, more complete version of the theory, the subject and sender were characterized by a dual contractual relation since not only will the subject actant have a contractual relation with the manipulating operator actant (sender) that institutes it as an operator subject but also performance is sanctioned by a final sender, whose absolute competence is presupposed (Perron and Fabbri, 1990).

In the surface narrative grammar, the object is one of the terms of the elementary utterance that when inscribed in a conjunctive or disjunctive relation with the subject guarantees the latter's semiotic existence. However, while remaining unknowable in itself, the object exists semiotically as a locus of fixation, a locus of clustering of the value determinations. Values invested in the object can only be accounted for syntactically, and it is in this syntagmatic unfolding that syntax joins semantics. Moreover, values can be apprehended as signification when they are converted from semantic into syntactic structures. Hence, conversion made it possible both to define narrativization as the syntagmatic emplacement of values and to perceive it as a discursive organization that manipulates the constitutive elements of the elementary utterance. Moreover, two broad categories of values – descriptive (consumable or storable objects, states and feelings) and modal (wanting-to-be/to-do, being-able-to-be/to-do, having-to-be/to-do, and knowing-how-to-be/to-do) – were defined. In turn, descriptive values can be divided further into subjective (essential values) and objective (accidental values), and in narrative programs base values were distinguished from instrumental ones that definitively fixed the first two stages of what has been defined as the 'standard theory' of the Paris School (Parret, 1989).

At the surface level, narrative was defined as the transformation of a series of utterances of state (conjunctive and disjunctive utterances) by a metasubject operator (utterance of doing). Such a syntactic organization made it possible to represent narrative as a series of virtualizations and actualizations of values. Values inscribed within a given axiological universe circulate in two ways. In the case of constant values between subjects in an isotopic and closed universe, they circulate as conflictual–polemic confrontation, whereas in the case of exchange, the presence of two objects of value is required, and this structure constituted a new virtualization and a new actualization. Simple exchange was then considered as a complex mode of value transfer at the level of surface syntax.

Nonetheless, cases in which exchange values are not identical for such an operation to take place require their preliminary identification by subjects, who, by fixing the exchange value of the objects of value, establish a fiduciary contract between themselves. When the objects of value are objects of knowing, or messages being communicated, and when the subjects are competent but unequally modalized, one of the fundamental organizing structures of narrative grammar, the polemic–contractual, is transposed into the very core of intersubjectivity. This is where, as Greimas (1983: 11) noted, "It seems to be able to account for the fiduciary, troubling and groping, but, at the same time, cunning and dominating nature of communication."

Within a closed universe, the contractual dimension of exchange in participatory communication is

ensured by a sender who guarantees the circulation of values. The latter corresponds to a mediating domain between an immanent universe and a transcendent universe that are manifested through the presence of actants at the surface level syntax. The source of the contract in discourse, the sender, is the disengaged representative of the paradigmatic system of the invested contents or the values that are the taxonomic constituents of the fundamental grammar (Courtés, 1976: 99). From this, it follows that the relation between the contractual sequence and the performance sequence is established by internalization of the conversion of the paradigmatic dimension in the narrative. If the subject–receiver accepts the contractual sequence as a narrative program, it is transformed into a performing subject if, and only if, it acquires modal competence that ensures the mediation between system and process, and realizes virtual values.

The narrative organization of values continues to be the foundation of narrativity insofar as it guarantees the semiotic existence of actants. The object of value – one of the terms of the elementary utterance previously defined as a semiotic simulacrum, representing our relation to the world in the form of a scene – is also a syntactic concept. The distinction between actants (considered initially as simple supports and then progressively invested by values through conjunctive and disjunctive relations) and actors (that can syncretize several actants) made it possible to explore the relations between elementary narrative structures and discursive structures.

As it progresses through its narrative trajectory, an actant can assume a certain number of narrative states or actantial roles that are defined by its position within the narrative trajectory (syntactic definition) and its modal investment (morphological definition). The subject actant will be endowed successively with the modalities of competence as a necessary step toward performance, and in this case the subject assumes those actantial roles that define the subject in terms of wanting-to-do, knowing-to-do, being-able-to-do, and having-to-do, which indicate the four states in the acquisition of its modal competence. Because they are defined morphologically by their modal content, and syntactically by the position of actant in the narrative trajectory, actantial roles are situated within narrative syntax. Nonetheless, when associated with thematic roles that structure the semantic component of the discourse, they allow for the construction of actors as loci where narrative and discursive structures converge and are invested (Greimas and Courtés, 1982: 6).

What first distinguishes an actantial role from an actor is that at the level of discourse an actor's semantic content is defined by the presence of the semes that are (i) figurative entity (anthropomorphic and zoomorphic order), (ii) animated, and (iii) subject to individuation. At the same level the actantial role appears, as a qualification, as an attribute of the actor. From a semantic point of view, this qualification is no more than the denomination subsuming a field of functions (i.e., behaviors actually noted in the narrative or simply implied). The minimal semantic content of role is identical to the concept of actor, despite the exception of a seme of individuation, which the former does not possess. Greimas (1970: 56) noted, "The role is an animated figurative entity, albeit anonymous and social. In turn, the actor is an individual integrating and assuming one or several roles." From this, it follows that there are three distinct levels of narrative interplay: Roles, which are elementary actanial units corresponding to coherent functional domains, are related to actants (elements of the narrative) and to actors (units of discourse).

The actor is thus seen as the point of investment of the syntactic and semantic components. To be designated as an actor, a lexeme must have both an actantial and a thematic role. To realize their potentialities, thematic roles in turn call into play the lexematic level of language and appear as figures that are integrated into discursive configurations. The final domain of the narrative trajectory or the figurative level of discourse is characterized by the investment of themes and values in figures. Figures, defined as figures of content that correspond to the figures of the expression plane of the natural semiotic system, when strung over sequences constitute their discursive configurations. The procedures of figurativization, the first of which can be described as figuration and the second as iconization, invest these figures with specificities that produce a referential illusion. One of the basic components of figurativization is the onomastic one. Figurativization specifies and particularizes abstract discourse. It is grasped in its deep structures and by the introduction of anthroponyms that correspond respectively to the procedures constitutive of discursivization, actorialization, spatialization, and temporalization on the plane of discursive syntax (Greimas and Courtés, 1982, 119–120).

While continuing to evolve a theory of narrativity in a further phase of his semiotic project, Greimas focused on constructing an actantial and semionarrative grammar developed as a modal and aspectual grammar. As he sensed the need to construct a better articulated elementary syntax, he abandoned the Proppian formulation of narrative in order to free the theory from concepts that remained too close to the manifest level of discourse. The first step consisted in reformulating surface narrative syntax in

terms of modalities. Starting with the definition of modality as that which modalizes a predicate of an utterance, modalization was then considered as the production of a modal utterance that overdetermines a descriptive utterance (Greimas and Courtés, 1982: 193). Defined in terms of the structure of the elementary utterance whose end terms are actant, utterances of doing or utterances of state were considered as the transformation of a conjunctive/disjunctive state. However, reformulating the act as that which causes to be permitted him to redefine it as a structure combining competence and performance, with performance presupposing competence, but not vice versa.

He then distinguished transitive relations defining the descriptive predicate between the subject and the utterance of doing both from veridictory relations established by a subject and an utterance produced by another subject and from factitive relations between the subject and object that already constitute an utterance of doing. These last two relations that occur between two hierarchical, distinct subjects – a cognitive subject and a pragmatic subject – constitute the simple modal structure. The advantage of reformulating the act in these terms is that it enabled him to develop a theory of performance in three directions: a semiotics of manipulation (or the manipulation of the subject by the sender), a semiotics of action (the acquisition of competence by the subject), and a semiotics of sanction (judgments on oneself and on other subjects).

When defining the Subject at the level of the organization of pragmatic competence, it was possible to identify four fundamental modalities: the modalities of having and wanting, which virtualize the process, and the modalities of being-able and knowing, which actualize it. However, because this canonical representation of competence does not always correspond to what happens at the level of manifestation, it was necessary to construct a model that could account for the fundamental modal structure by subsuming its diverse articulations through a series of interdefinitions. The criteria of interdefinition and classification of modalities is simultaneously syntagmatic and paradigmatic; each modality is defined both as a hypotactic modal structure and as a category that can be represented on the semiotic square.

Within the confines of a theory of modalities, another area of investigation mapped out focused on procedures leading to the epistemic act. When situated at the level of surface narrative (manipulation, action, and sanction), both persuasive and interpretative activity (doing) were defined as cognitive procedures that, in the first case, end up as causing-to-believe and, in the second, as an act of believing (i.e., as an epistemic act). The epistemic act was then defined as a transformation that, when articulated on the semiotic square (to affirm, to refuse, to admit, or to doubt), at the level of surface syntax appears as a series of hierarchically linked narrative programs. Epistemic modalizations can also be represented as modalities and junctive operations, and before becoming act, or operation (which is of the order of doing), a modal competence or the being of the doing is presupposed on the part of the subject. After noting that transactions engage the subjects in a fiduciary contract, communication was defined in terms of contract propositions, which in fact are presuppositions to communication. Situated within a semiotics of manipulation and sanction, cognitive space was considered to be the locus for manipulation based on knowing, whereby a subject transforms another into a convinced subject and submits it to judging epistemic activity on the part of a final subject.

However, since the initial definition of the epistemic act converted the elements of the square onto the surface syntax, not as contradictions but as linear gradations, Coquet (1985) noted that this type of semiotic square represented an important development in 'syntagmatic rationality.' Technical thinking of an algorithmic nature that was founded on objective modal necessity (i.e., on a/not-being-able-to-not-be/) was opposed to practical thinking of a stereotypical nature that depends on the co-occurrence, in temporal contiguity, of acts – or the utterances that describe them – whose succession was considered predictable and therefore plausible or even necessary. At the surface level of discourse, causal reason, or syntagmatic rationality, was further defined in terms of technical thinking and practical thinking. Yet, parallel thinking led to the discovery of the bi-isotopic nature of discourse based on the appearance of the implicit characterizing figurative discourses that, when dereferentialized, create a new referent or thematic level. (The concept of isotopy designates both the repetition of classemes and the recurrence of semic categories, be they thematic or figurative.) By projecting a double reference (one that moves deeper and creates a more abstract thematic isotopy, and one that moves laterally and develops a new parallel figurative isotopy), parallel discourse constitutes an original type of syntagmatic articulation. Figurative models such as parables, allusive in nature, were given as an example of figurative reasoning. Projected by the sender, these models, which are fiduciary by definition and of the order of subjective/having-to-be/, were opposed to homological thinking, which introduces mathematical proportion into the evaluation of the relations between isotopies presumed to be parallel. Greimas (1987: 179) further refined the theoretical foundations of modal grammar when he studied

the relations between the fiduciary and the logical within a cognitive universe. He defined this universe as a network of formal semiotic relations from among which the epistemic subject selects equivalencies it needs in order to receive veridictory discourses and thereby demonstrates that believing and knowing are part of the same cognitive universe.

Greimas turned to the modality of being after having analyzed the modality of doing. As Coquet (1985) noted, this analysis completed the study of the actions of the subject (modal competence) and set the way to the study of their passions (modal existence) within the context of a modal grammar reformulated along the lines of surface narrative syntax. Thymic space, which at the deep level represents the elementary manifestations of a living being in relation to its environment (animated), at the surface level is converted into modal space appearing as an overarticulation of the thymic (human) category. Yet, in any utterance, the subject's semiotic existence is determined by its relation to the object of value and the modalizing of being considered as the modifications of the status of the object of value. The modalities affecting the object (or, rather, the value invested therein) are said to be constituents of the subject of state's modal existence. A taxonomic network for modal syntax was worked out by projecting the modal utterances onto the semiotic square (wanting-to-be [desirable for the subject of state], having-to-be [indispensable], being-able-to-be [possible], and knowing-how-to-be [genuine]). The same interrelations that were discovered when analyzing the modalization of doing were discovered here, and a syntax of modalized values was worked out based on elementary narrative syntax.

It was shown that thymic values are converted from the deep level when invested with syntactic objects defined by conjunctive/disjunctive relations with subjects. As Parret and Ruprecht (1985) perceptively noted, this conversion profoundly affects value by placing it under subjectivity and its intentionality. At the theoretical level, it then became possible to pragmatize Greimas's semiotics by introducing tensivity and graduality in the deep structures. Also, the theory was freed up "from the notion that at the deep level values are economical (in the Saussurian sense) and at the surface level they are graduated and tensive" (xlvii). The introduction of modality theory and the working out of conversion procedures were decisive steps in establishing an integrated theory of narrativity.

It was suggested that the problematic of passions is linked to the study of the modal existence of the subject, and more precisely to the modal component of the actantial structures. Whether the object of investigation happens to be a lexeme-passion such as anger – considered as a virtual narrative trajectory – or, on the contrary, passional stories that are realized narrative syntagms, as Landowski (1979: 8) remarked, the exploration of the field of passions closely involves all of the levels of the articulations of the theory of narrativity:

> This includes not only the semionarrative structures proper (instances of passions being identifiable by their underlying modal and actantial structures), not only the discursive structures (aspectualization, actorialization, semanticization of the underlying syntagma), but also the deep level abstract structures.

In contradistinction to action, which was defined as a syntagmatic organization of acts, passions were considered as the syntagmatic organization of states of feeling or the discursive aspect of the modalized being of narrative subjects (Greimas and Fontanille, 1993). Passions, which are either simple or complex (a syntagmatic intertwining of states and of doing), are expressed through actors and, along with actions, determine the roles (actantial and thematic) they realize. Thus, the opposition between action and passion represents the "conversion on the discursive level of the deeper and more abstract opposition between being and doing, or more specifically between modalized being and modalized doing" (Greimas and Courtés, 1986: 162).

The subject's being, whether, for example, in simple or in fiduciary expectation, is first modalized by the modality of wanting, which actualizes (wanting-to-be-conjoined) in order then to be realized (i.e., to be conjoined with the object of value). It is this very conjunction that guarantees the subject's semiotic existence. Whether at the semiotic or at the discursive level, the notion of value, which we also saw with regard to the doing of the subject, is at the very heart of the theory. Thus, parallel to the trajectory of the subject of doing made up of the acquisition of competence and the accomplishment of performances, there exists a comparable trajectory of the subject of state, presented as successions of 'feeling states' made up of highs and lows. Consequently, the modalization of the subject's being has an essential role in the constitution of the competence of syntactic subjects, and the concept of passion is closely linked to that of actor. Passion thus becomes "one of the elements that contribute to actorial individuation, able to offer denominations for recognizable thematic roles ('the miser,' 'the quick-tempered,' 'the unconcerned,' etc.)" (Greimas and Courtés, 1986: 162–163). Moreover, the linking of passions to actors and the investigation of relations between thematic roles and actantial roles has opened up a new domain of research into passional typologies.

Within the framework of traditional theories of passions (i.e., Descartes, Spinoza, Leibniz, Nietzche, and Freud), Greimas's strategy was to work out semiotics of passions, a pathemic semiotics founded on his own previously elaborated semiotics of action. However, to ensure that the theory maintained its coherence by conforming to the principles of hierarchy and interdefinition, it was necessary to establish descriptive procedures that integrated all prior definitions of the actional dimension into the pathemic one. The reasons for adapting such descriptive strategies and tools were partially related to the fact that Greimas drew heavily on Husserl and Merleau-Ponty's works in phenomenology. For him, the subject's relation to the object was mediated by the body, which is at the same time part of the world and subject. Moreover, the body was also seen as an object situated between other objects and the world and at the same time the point of view from which the world is experienced. The body was defined as both action on the world and a perceiving, a sensing of the world. From this perspective, it is evident that Greimas greatly distanced himself from Ferdinand de Saussure, for whom the sign was a totally disembodied concept. For the latter, there was no place for perception, or for the body, nor did there exist a chasm between subject and object. Along these same lines, Greimas escaped from another common dualistic philosophical assumption of a separate subject and object, subject and world – the activity of the former being to understand that of the latter and nothing else. However, as was noted in discussing modalization, passion paradoxically is a phenomenon in which the object, in becoming a value for the subject, imposes itself on the subject. The action of the world on the subject and the action of subject preceding the world as value became crucial in pathemic configurations (Perron and Fabbri, 1993).

What Greimas and Fontanille attempted to do was to present a more or less coherent foundation to complete the semiotic theory begun approximately 25 years previous. To do this, they started from an intuition and imagined positions that made it possible for them to polarize the universe. This enabled them, on the one hand, to postulate a sort of prototype of an actant, linked by Hegel to intentionality and rearticulated by Husserl as the protensivity of the subject, a sort of minimal state of the subject who is not yet a subject but simply a subject striving for something. On the other hand, they envisioned a sort of potentiality of the object, which enabled them to consider the world as value. What now appears to be the thorniest issue in the theory is the issue of the object and not that of the subject. To understand subjects as being, as meaning, they must be defined by the values they acquire. From this viewpoint, the semiotics of passions became a semiotics of the values acquired, lost, suspended, and so on by the subject. What we are dealing with is a subject defined by its protensivity, faced with an object of value that is unformed, a shadow of the value that can be semanticized. In a later phase, the value became the valence, which then led to the question of the value of value. In brief, whether examining the semiotics of passions or the semiotics of aesthetics, the two main domains of current investigation, Greimassian semiotics has as its fundamental preoccupation the issue of value.

In concluding, it should be noted that Greimas found the inspiration and the sources of his work in two of the great 20th-century scholars of anthropology and folklore. Lévi-Strauss provided him with the paradigmatic cover of the theory and Propp with the syntagmatic or syntactic one. After working out the necessary theoretical mediations, he linked together two complementary models and constructed a theory that could be generalized in terms of a general narrative semantics. He then freed the theory from Propp's formula of the tale as a means of analyzing narrative, and an elementary syntax that could organize any types of discourse was developed. Propp's model was broken down into three successive sequences that correspond to the syntagmantic unfolding of the actantial model (paradigmatically articulated in a quest sequence (subject → object) and a communication sequence (sender → object → receiver)), in which two sequences of communication frame an action sequence. The mandate sequence and the evaluation sequence bracket the action sequence that transforms the states. From this, a semiotics of manipulation was established – how the sender manipulates the subject; then a semiotics of action – how competence is acquired to carry out performance; and finally a semiotics of evaluation or sanction.

At the same time, attempts were made to construct a model of meaningful actions in an intersubjective frame. Greimas first worked out a model of actions before introducing notions such as modalities and aspectualities that overdetermine the actants. He posited and interdefined four fundamental modalities (two virtual ones and two actualizing ones), as well as three aspectualities (inchoativity, durativity, and terminativity). Then, because folktales were considered as an intersection between two conflictual and contractual actions in progress, Greimas was able to transform the Proppian model into an interactional one. Instead of a subject, an object, and an opponent, two modally competent interacting subjects were postulated. Each subject, with its own modal organization, was situated in a polemicocontractual relation to

the other. Strategy became more important than rules. Moreover, in addition to the system of modalities, the actantial model was able to define the construction and transmission of meaning. Due to the work of Marcel Mauss and Lévi-Strauss, communication was rethought in terms of exchange and challenge, and the concept was extended from the circulation of objects and messages to the exchange of modal values within the framework of a fiduciary contract that must be maintained actively during interaction.

The opening of the fiduciary dimension introduced the subject matter of belief and adhesion in the cognitive dimension, which raises at least two orders of questions: the relevance of the figurative component and that of the passional one. Through the mediation of the enunciative instance, the virtual structures of action are realized and figurativized differently according to the categories of the natural world employed as forms of expression. Regarding the passional dimension, it became possible to give an operational account of the emotional systems and processes – in other words, the transformation of the states of feeling of the subject with respect to the actions that incite them and the actions they lead to (Greimas, 1987: 148–164, 1990: 160–174). When dealing with figurativity we encounter the problem of the typology of signs, especially nonlinguistic and nonarbitrary signs, and their efficacy. When dealing with passions we are basically concerned with the stringing of modalities, tensitivity, thymism, and in general with the dimension of bodily propioceptivity.

Throughout this article, in which the salient features of Greimas's semiotic were traced, an attempt was made to highlight the constructed and hypothetico-deductive aspect of a theory in which concepts are interdefined and hierarchically ordered. The anthropomorphic dimension of the global theory, conceived of as an ongoing scientific project founded on internal coherence as a precondition to formalization, was also emphasized. Furthermore, three major phases were identified (formulation, narrative grammar, and modal and aspectual grammar), the manner in which research began on deep structures was discussed, semionarrative structures were explored, and surface (discursive and figurative) structures were then analyzed. However, one should not conclude that the transpositional semiotic theory presented here is in any way a fully completed theory since research is currently being carried out on the pathemic, ethical, and aesthetic dimensions of discourse. This should contribute to the construction of the semionarrative grammar, and further work on aspectualities should lead to the development of an integrated and complementary discourse grammar.

Action Sentences

Philosophers have a long-standing interest in the distinction between the things that people do and the things that merely befall them. This interest stems from a deeper concern with the concept of intentional action and the nature of human agency. Many distinguished philosophers have sought to illuminate this distinction by looking at how actions are described in natural language and what such descriptions imply about the agents of an action and the role of their intentions in the events described.

It is difficult to get at the distinction in a principled way. The problem is especially acute for sentences like (1):

(1) Phillip made Sally fall into the well.

Example (1) can be made true either by Phillip's deliberate pushing of Sally into the well or by his having accidentally done so. Likewise, a sentence such as:

(2) John's hand rose

does not imply that the raising of John's hand was the result of anything that John did. Compare this with:

(3) John raised his hand

which is true only if John intentionally raised his hand. Example (3), but not (2), implies that the raising of John's hand was an **action** of his, that he intended to raise his hand and that this intention was the reason why his hand rose when it did. But does this difference in how the truth conditions of (3) might be constituted reflect a corresponding semantic difference? Is (3) actually ambiguous?

I will look at two popular ways of capturing the properties of action sentences, starting with one rooted in philosophical logic, the other more closely related to natural language semantics. One of the main traditions is tied to the logic of the deontic modalities, i.e., the logic of obligation. Just as one might translate sentences of the form *α is obligated to Φ* with a special operator with *It is obligatory for α that α Φ*, so one might capture the agentive sense of a sentence of the form *α Φ-ed* with *It was intentional of α that α Φ-ed*. Some other proposals for paraphrasing are illustrated in examples (4) and (5).

(4a) John swam the channel.
(4b) John brought it about that he swam the channel.

(5a) Sam brought the pie.
(5b) Sam made it the case that he brought the pie.

One can still wonder whether these paraphrases really capture the agentiveness of these constructions. Looking just at (4a), there are a number of ways in which one can bring about the swimming of the channel, not all of them having to do with one's intentionally swimming the channel. Similar remarks apply to *making it the case that*. Not all of what I can intuitively be said to have made the case originates in something I intended to do.

A notable development in this area, one which appears to escape some of the problems of earlier views, is the work Nuel Belnap, along with several colleagues. They treat

(6) John opened the door

on its agentive reading as equivalent to

(7) John saw to it that the door opened.

Action Sentences

Philosophers have a long-standing interest in the distinction between the things that people do and the things that merely befall them. This interest stems from a deeper concern with the concept of intentional action and the nature of human agency. Many distinguished philosophers have sought to illuminate this distinction by looking at how actions are described in natural language and what such descriptions imply about the agents of an action and the role of their intentions in the events described.

It is difficult to get at the distinction in a principled way. The problem is especially acute for sentences like (1):

(1) Phillip made Sally fall into the well.

Example (1) can be made true either by Phillip's deliberate pushing of Sally into the well or by his having accidentally done so. Likewise, a sentence such as:

(2) John's hand rose

does not imply that the raising of John's hand was the result of anything that John did. Compare this with:

(3) John raised his hand

which is true only if John intentionally raised his hand. Example (3), but not (2), implies that the raising of John's hand was an **action** of his, that he intended to raise his hand and that this intention was the reason why his hand rose when it did. But does this difference in how the truth conditions of (3) might be constituted reflect a corresponding semantic difference? Is (3) actually ambiguous?

I will look at two popular ways of capturing the properties of action sentences, starting with one rooted in philosophical logic, the other more closely related to natural language semantics. One of the main traditions is tied to the logic of the deontic modalities, i.e., the logic of obligation. Just as one might translate sentences of the form *α is obligated to Φ* with a special operator with *It is obligatory for α that α Φ*, so one might capture the agentive sense of a sentence of the form *α Φ-ed* with *It was intentional of α that α Φ-ed*. Some other proposals for paraphrasing are illustrated in examples (4) and (5).

(4a) John swam the channel.
(4b) John brought it about that he swam the channel.

(5a) Sam brought the pie.
(5b) Sam made it the case that he brought the pie.

One can still wonder whether these paraphrases really capture the agentiveness of these constructions. Looking just at (4a), there are a number of ways in which one can bring about the swimming of the channel, not all of them having to do with one's intentionally swimming the channel. Similar remarks apply to *making it the case that*. Not all of what I can intuitively be said to have made the case originates in something I intended to do.

A notable development in this area, one which appears to escape some of the problems of earlier views, is the work Nuel Belnap, along with several colleagues. They treat

(6) John opened the door

on its agentive reading as equivalent to

(7) John saw to it that the door opened.

Adoption of a special operator *stit* (α sees to it that: p) also allows them to capture some of commonalities between action verbs and imperatives, e.g., the fact that imperatives can only be formed felicitously from action verbs. One might worry, though, about the relations the proposed paraphrases have to the meanings of natural language sentences.

Another, popular way of approaching action sentences comes from Donald Davidson. Rather than rendering action sentences in a notation specifically designed to capture the concept of intentional action, e.g., *stit* operators and the like, one seeks to illuminate the semantic properties of action sentences by looking at what a general theory of meaning for the language containing those sentences tells us.

More specifically, the signature move in Davidson's paper was to posit, alongside the overt arguments of the verb, an additional argument place whose value is an event. One natural way of capturing this thought is to look at ordinary ways of classifying objects. A common noun N predicated of an object x classifies x as an N – a chair, a book, etc. Likewise for verbs, if events are taken to be values of variables just as concrete objects are: a verb V predicated of an event e classifies e as a V-ing, e.g., as a pushing or a swearing, etc. The original formulation of Davidson's proposal, ignoring tense, is this:

(8a) John kissed Mary
(8b) $\exists e$[kiss(John, Mary, *e*)

The extra argument place in (8b) is for an event. An early modification of Davidson's view is to make (8b) a bit more complex.

(8c) $\exists e$[AGENT(John, *e*) & kiss(*e*) & PATIENT(Mary, *e*)]

Informally, what this says is that there is a kissing whose agent is John and whose patient is Mary, i.e., there is a kissing of Mary by John.

Davidson's views have been influential, both in inspiring further work and in attracting critical attention. For example, what does one say about sentences like:

(9) I haven't eaten breakfast.

Surely, one does not want an utterance of (9) to mean that there is no past event of my having eaten breakfast. Views taking Davidson's work as a point of departure include the work of Jennifer Hornsby (1980) and George Wilson (1989). Pietroski (1998) and Lombard (1986) discuss some of other criticisms, suggesting modifications.

Adverbs

Adding events to the toolkit of philosophers and philosophically minded linguists also enabled new treatments of adverbs. There is perhaps no single reason why philosophers have been interested in adverbs. But a good deal of what is of interest to philosophers has to do with the metaphysics of events or, in terms that partly overlap with talk of events, occasions, happenings, situations, and states of affairs. For example, a good many philosophers have wanted to acknowledge different classes of events, e.g., states, processes, achievements, and so on. See Vendler (1967), Bennett (1988), and Steward (1997). One way to approach these issues is by looking at how adverbs modify verbs that apply to these different sorts of events.

I will look at two families of theories of adverbs, beginning with an application of Davidson's view of action sentences. Just as adjectives modify nouns, so adverbs modify verbs. The following analysis is nearly unavoidable for many adjectives:

$[_{NP}$ Adj [N]] $\Rightarrow$ [Adj(x) & N(x)]

Thus, the denotation of, e.g., 'nice dog' is something that is both nice and a dog. Davidson's event analysis of action verbs gives a parallel, conjunctive analysis of adverbial modification:

$[_{VP}$ Adv [V]] $\Rightarrow$ [Adv(e) & V(e)]

The grammatical combination of an adverb with a verb is to be interpreted as the predication of two predicates about an event. The parallel with nominal modification is preserved. The theory also works for phrasal modification of verbs, e.g., for prepositional phrases such as *in the school*, *at five o'clock*, *after he took the kids to school*, etc. A sentence such as (10a) is represented as (10b):

(10a) Sam sang loudly in the shower
(10b) $\exists e$[AGENT(Sam, *e*) & sang(*e*) & loud(*e*) & in the shower(*e*)]

In words: there was a singing by Sam in the shower and it was loud.

Any theory of adverbial modification should show why the following inferences are valid:

(11) Sally broke the eggs quickly in the sink
(12) Sally broke the eggs quickly
(13) Sally broke the eggs in the sink
(14) Sally broke the eggs
(15) Sally broke something in the sink.

Example (11) logically implies (12) and (13), both of which imply (14). Additionally, (11) and (13), although neither (12) nor (14), imply (15) by themselves. A large number of adverbial modifiers permit detachment inferences. These inferences are immediate on the event-based theory.

Even with these virtues though, Davidson's theory does not readily extend to adverbs such as *halfway* or *partly*, e.g.,

(16) John walked partly to the store
(17) Alex halfway filled the glass with juice.

It does not seem to make any sense to talk about events that are, for example, halfway in and of themselves, although there are events that are halfway fillings of glasses. It seems as though the adverb forms up a complex predicate with the verb rather than standing alone as a predicate of an event. More seriously though, as easily as the theory handles cases such as *John swam quickly to the shore*, there is no obvious way of extending it to *John allegedly climbed the garden trellis*. There is no event that is both alleged as well as a climbing. See Larson (2001) and Taylor (1985) for further discussion.

Perhaps the most influential way of treating adverbs is to take them to be quantificational in some respect or as forming up intensional operators (Cresswell, 1986 Lewis, 1975). This helps with sentences such as (18) and (19).

(18) John probably left in a hurry.
(19) George frequently left a chocolate on his son's pillow.

Here, an adverbial appears to modify not the event picked out by the predicate, i.e., the leaving, but the whole proposition, i.e., John's leaving in a hurry. A theory having only events at its disposal is ill equipped to handle these cases. On the other hand, a theory incorporating propositions and intensions and quantification over possible worlds seems to be in comparably better shape to handle these kinds of contexts.

Further, if one treated adverbs as properties of events, it is much easier to treat sentences that contain negations such as the following:

(20) Rob cleverly didn't catch a fish.

Here, one might say that Rob's not catching a fish has the property of being clever. Another important advantage of a view like this is that it affords a nice treatment of indefinite noun phrases such as *a fish* or *a chocolate* in the scope of an adverb such as *frequent*. This can be seen in sentence (19) or in (21) and (22) below:

(21) Lisa often found a missing check in the Chairman's desk
(22) Alex repeatedly felt an odd tickle on his toe.

Example (21) is perhaps best read as implying that it is often enough the case that Lisa, when looking in the chairman's desk, found a check that was missing. And (22) is not best interpreted as implying that there is some one odd tickle that is felt repeatedly by Alex. Rather, what the sentence is most naturally understood as saying is that there was a set of odd tickles in Alex's toe that was repetitive. The quantificational view is further developed by Thomason and Stalnaker (1975) and by McConnell-Ginet (1982).

Active/Inactive Marking

C Harris, State University of New York at Stony Brook, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction and Definition

A marking system is said to be of the active/inactive type if subjects of transitives and of one subset of intransitives are associated with one marker, while direct objects and subjects of remaining intransitives are associated with a different marker. Verbs whose subjects pattern with those of transitives are often referred to as active intransitives, while those whose subjects pattern with direct objects may be called inactive intransitives.

For example, in Georgian, a language of the Kartvelian family, in one set of tense-aspect-mood paradigms, subjects of transitives and of active intransitives bear the *-ma* case marker, while subjects of inactive intransitives and direct objects bear the *-i* case.

(1) monadire-eb-ma nax-es irem-i
hunter-PL-ACT *saw-3*PL*S* *deer*-INACT
'The hunters saw a deer.'

(2) bavšv-eb-ma ičxub-es
child-PL-ACT *quarreled-3*PL*S*
'The children quarreled, fought.'

(3) bavšv-eb-i saxlši darč-nen
child-PL-INACT *house.in* *stayed-3*PL*S*
'The children stayed in the house.'

In order to treat all languages discussed in this article in a parallel way, the *-ma* case is here glossed 'active' (ACT), but it is usually called by the rather misleading name 'ergative' or by the relatively meaningless name 'narrative.' The *-i* case is usually called 'nominative' but here is glossed as 'inactive' (INACT). In the descriptions of other languages, a variety of terms are traditional.

What makes the pattern in (1–3) active/inactive marking is the fact that one case, the active, is used for the subject of the transitive (in (1)) and of the active intransitive (in (2)), while a different case, the inactive, is used for the subject of the inactive intransitive (in (3)), and for the direct object, *iremi* 'deer,' of the transitive (in (1)).

Notice that the subjects of the transitive verb in (1) and the active intransitive verb in (2) condition the third person plural subject agreement marker *-es*, while the subject of the inactive intransitive verb in (3) conditions the agreement marker *-nen* for the same person and number in the same tense. Although the two types of intransitives differ with respect to agreement, this agreement pattern does not satisfy the definition of active/inactive marking, since the marker *-nen* used for subjects of inactive intransitives is not also used for direct objects, as can be seen in (4).

(4) monadire-eb-ma nax-es irm-eb-i
hunter-PL-ACT *saw-3*PL*S* *deer*-PL-INACT
'The hunters saw some deer.'

The plural direct object in (4) does not condition the marker *-nen*, and thus agreement in Georgian is not active/inactive. In fact, most agreement in Georgian marks all subjects of a particular person and number combination without regard to verb type. Agreement in the aorist is presented in (5).

(5)

	Singular	Plural
1st	v–	v–t
2nd	–	–t
3rd	–a	–es/-nen

While case marking of NPs is active/inactive in (1–3), none of the agreement in this language is of the active/inactive type.

However, true active/inactive agreement is found in Creek (Muskogee), a member of the Muskogean family.

Active/Inactive Marking

Introduction and Definition

A marking system is said to be of the active/inactive type if subjects of transitives and of one subset of intransitives are associated with one marker, while direct objects and subjects of remaining intransitives are associated with a different marker. Verbs whose subjects pattern with those of transitives are often referred to as active intransitives, while those whose subjects pattern with direct objects may be called inactive intransitives.

For example, in Georgian, a language of the Kartvelian family, in one set of tense-aspect-mood paradigms, subjects of transitives and of active intransitives bear the *-ma* case marker, while subjects of inactive intransitives and direct objects bear the *-i* case.

(1) monadire-eb-ma nax-es irem-i
hunter-PL-ACT *saw-3*PL*S* *deer*-INACT
'The hunters saw a deer.'

(2) bavšv-eb-ma ičxub-es
child-PL-ACT *quarreled-3*PL*S*
'The children quarreled, fought.'

(3) bavšv-eb-i saxlši darč-nen
child-PL-INACT *house.in* *stayed-3*PL*S*
'The children stayed in the house.'

In order to treat all languages discussed in this article in a parallel way, the *-ma* case is here glossed 'active' (ACT), but it is usually called by the rather misleading name 'ergative' or by the relatively meaningless name 'narrative.' The *-i* case is usually called 'nominative' but here is glossed as 'inactive' (INACT). In the descriptions of other languages, a variety of terms are traditional.

What makes the pattern in (1–3) active/inactive marking is the fact that one case, the active, is used for the subject of the transitive (in (1)) and of the active intransitive (in (2)), while a different case, the inactive, is used for the subject of the inactive intransitive (in (3)), and for the direct object, *iremi* 'deer,' of the transitive (in (1)).

Notice that the subjects of the transitive verb in (1) and the active intransitive verb in (2) condition the third person plural subject agreement marker *-es*, while the subject of the inactive intransitive verb in (3) conditions the agreement marker *-nen* for the same person and number in the same tense. Although the two types of intransitives differ with respect to agreement, this agreement pattern does not satisfy the definition of active/inactive marking, since the marker *-nen* used for subjects of inactive intransitives is not also used for direct objects, as can be seen in (4).

(4) monadire-eb-ma nax-es irm-eb-i
hunter-PL-ACT *saw-3*PL*S* *deer*-PL-INACT
'The hunters saw some deer.'

The plural direct object in (4) does not condition the marker *-nen*, and thus agreement in Georgian is not active/inactive. In fact, most agreement in Georgian marks all subjects of a particular person and number combination without regard to verb type. Agreement in the aorist is presented in (5).

(5)

	Singular	Plural
1st	v–	v–t
2nd	–	–t
3rd	–a	–es/-nen

While case marking of NPs is active/inactive in (1–3), none of the agreement in this language is of the active/inactive type.

However, true active/inactive agreement is found in Creek (Muskogee), a member of the Muskogean family.

(6) Ci-hîic-ey-s (Martin, 1991: 96)
*2*INACT-*see*. FGR-*1*SACT-DCL
'I see you.'

(7) Tâask-ey-s (Martin, 1991: 97)
jump.FGR-*1*SACT-DCL
'I jumped.'

(8) Ca-tahópk-ii-s
*1*SINACT-BE.NIMBLE-DUR-DCL
'I'm nimble, limber.'

(AUX = auxiliary, FGR = falling tone grade, DCL = declarative, DUR = durative, HGR = h-grade, LGR = lengthened grade, SS = same subject.)

The suffix *-ey* marks the first person singular subject of the transitive in (6) and of the active intransitive in (7), while the prefix *ca-* marks the first person singular subject of the inactive intransitive in (8) and the first person singular direct object of transitives (not illustrated). The complete sets of markers of the first type (glossed with ACT) and of the second type (glossed with INACT) are given in (9) and (10), respectively.

(9) Set I (active)

	Singular	Plural
1st	-ay (-ey, -a)	-iy (-ii)
2nd	-íck (-ícc, ´-ck, ´-cc)	-áack (-áacc)

(10) Set II (inactive)

1st	ca- (aca-, acaa-)	po- (ipo-, ipoo-)
2nd	ci- (ici-, icii-)	

As indicated in (10), the second person marker of the inactive set (shown in (6)) does not distinguish singular from plural. Third person agreement is not marked by either set.

While verb agreement distinguishes an intransitive like that in (7) from one like that in (8), case marking in Creek does not make a parallel distinction. All subjects are marked the same, including subjects of transitives, (11), active intransitives, (12), and inactive intransitives (13).

(11) ma honanwa-**t** ifa-n nafêyk-it-oo-s
that man-NOM *dog*-ACC *hit*.HGR-SS-AUX-DCL
'That man hit the dog.'
(Martin, 1991: 116)

(12) ma honanwa-**t** taask-it-oo-s
that man-NOM *jump*.LGR-SS-AUX-DCL
'That man is jumping.'
(Martin, 1991: 106)

(13) ma honanwa-**t** áls-ii-t-ôo-s
that man-NOM *bashful*-DUR-SS-AUX-DCL
'That man is bashful.'

As we can see, in Creek, verb agreement follows the active/inactive pattern, but case marking does not.

Thus, we cannot say that a (whole) language is active/inactive; rather, some specific phenomenon may have active/inactive marking. In Creek, verb agreement is active/inactive, while case marking is nominative/accusative. In modern Georgian, case marking is active/inactive, while verb agreement is not.

While most of the active intransitives are always intransitive, some may have an optional direct object. An example from Georgian is given in (14).

Table 1 Comparison of major marking types

	Transitive subject	*Intransitive subject*		*Transitive object*
		Active	*Inactive*	
Nominative/ accusative	A		A	B
Active/ inactive	A	A	B	B
Ergative/ absolutive	A		B	B
Tripartite	A		B	C

(14) bavšv-eb-ma itamaš-es nard-i
child-PL-ACT *play*-3PLS *backgammon*-INACT
'The children played backgammon.'

Verbs of all types may cooccur with an indirect object, but the status of indirect objects differs from language to language. An example from Georgian of an indirect object with an inactive intransitive is given in (15), and an example with an active intransitive, in (16).

(15) merab-i m-elodeb-a
Merab-INACT *1SGIO-wait-3SGS*
'Merab is waiting for me.'

(16) merab-ma m-iq'vir-a
Merab-ACT *1SGIO-yell-3SGS*
'Merab yelled to me, at me.'

Thus, indirect objects are irrelevant to active/inactive marking.

Active/inactive is a marking type parallel to nominative/accusative, ergative/absolute, or tripartite marking. Table 1, adapted from Sapir (1917), compares these marking types; A, B, and C represent distinct cases, distinct agreement markers, or other marking.

As should be clear from Table 1, active/inactive is not a version of ergative/absolute marking, though it has sometimes been discussed in this way. In fact, one can still find active/inactive marking referred to as ergative following the tradition in some language families (such as Georgian), but not in languages where the tradition is different (such as Creek, other Muskogean languages, and indeed other languages of North America).

Variability in Case Marking

In general in the languages already described in this article, an intransitive verb form is strictly classified as requiring active or inactive marking, and use of alternative marking is ungrammatical. For example, if the case marking in the Georgian intransitives in (2)

and (3) is changed, the sentences are ungrammatical, whether or not the agreement markers are also changed. In contrast to this, there are some languages where, without special verbal morphology, some intransitives can be used either with the marking otherwise used for subjects of transitives ('active' marking) or with that used for direct objects ('inactive' marking). This is known as variable or fluid marking. For example, in northern Pomo, a Pomoan language of northern California, there is a set of intransitives whose sole argument is always in the inactive case, another set whose sole argument is always in the active case, and a third set whose subjects make use of both (O'Connor, 1992). The inactive intransitives include verbs such as *balay-banem* 'bleed', *xamal-c 'iko:m* 'feel upset', and *miboḥ* 'be bloated', while the set of active intransitives includes *k'otam* 'swim', *thaʔ* 'play', *habaša:čiʔ* 'make a verbal error, misspeak'. The verbs with variable marking include those illustrated in (17) and (18).

(17) ʔa: / to: šinu:-č-ade
1s.ACT *1s.INACT* *be.drunk-PROSP*
'I'm going to get drunk.'
(O'Connor, 1992: 209)

(18) ʔa: / to: diṭhal-e
1s.ACT *1s.INACT* *be.sick-PRES*
'I am/was sick.'
(O'Connor, 1992: 217)

In (17), when the active variant of the first person singular pronoun, *ʔa:*, is used, the sentence is a statement of intention; while when the inactive variant, *to:*, is used, the sentence is a "prediction about effects of current behavior" (O'Connor, 1992: 209). Thus, the difference in case seems to reflect a difference in volition and control (also referred to as agentivity). Yet in (18), the verb cannot be interpreted as agentive, and O'Connor argues that the first variant, with active case marking, is a neutral report, while the second is more expressive. (The northern Pomo facts are much more complex than these examples reveal; this description is based on only one set of formal contrasts.)

In some ways, the facts of Tsova-Tush (Bats), a language of the Nakh subgroup of the North East Caucasian family, are similar (see Holisky, 1984, 1987). Subjects of transitives are in the active case, and direct objects in the inactive. Third person subjects of intransitives are always in the inactive case, except with a tiny group of verbs. Thus, case marking of third person generally follows a strictly ergative pattern, but for first and second persons the facts are different in intransitives. First and second person subjects of one set of verbs are always in the active case; these include *egar* 'enter, mix with a group', *letxã ixar* 'dance', and *axar* 'bark.' First and second person subjects of another set are always in the inactive case, including *maicdar* 'be hungry,' *qerl'ar* 'be afraid,' and *daq'dalar* 'dry up.' First and second person subjects of some verbs can be in either case.

(19) (as) vuiž-n-as
1s.ACT *fell-AOR-1s.ACT*
'I fell down, on purpose.'
(Holisky, 1987: 105)

(20) (so) vož-en-sO
1s.INACT *fell-AOR-1s.INACT*
'I fell down, by accident.'

Holisky notes that differences between the forms of the stem and aorist suffix in the two examples are the effects of regular phonological processes. The parentheses indicate that the independent pronouns are generally dropped, but their case forms are reflected in the forms of the agreement suffixes, *-as* and *-sO* (with a reduced *o*).

The Relation to Unaccusativity

The Unaccusative Hypothesis, first proposed in Perlmutter (1978), is based on the observation that a number of languages make a distinction between two types of intransitives – unergatives and unaccusatives. The Unaccusative Hypothesis is a proposal that verbs of the latter type have a deep structure direct object but no deep structure subject, while unergative verbs have a deep structure subject and do not subcategorize a direct object (that is, they have a direct object optionally, if they have one at all). Perlmutter proposes in addition that the structural difference is semantically motivated. Harris (1981, 1982) suggests that active/inactive case marking in Georgian is one instantiation of the unergative/unaccusative dichotomy, and Davies (1986) makes a similar proposal for active/inactive agreement in Choctaw, a Muskogean language similar in this respect to Creek. This approach relates active/inactive marking to syntactic phenomena such as auxiliary selection in Italian and other languages.

Perlmutter (1978) draws attention to semantic subsets of verbs that seem to correspond cross-linguistically, and Levin and Rapaport Hovav (1995) and many others have continued to study cross-linguistic aspects of the lexical semantics of both types of intransitives (see the overview in Alexiadou *et al.*, 2004). Holisky (1981) explores in depth the lexical semantics of unergative verbs in Georgian, and she shows, for example, that Georgian verbs that express what light does (such as 'shine', 'sparkle', 'glitter') pattern with other verbs that occur with an active-case subject. Verbs with these semantics behave in the

same way in a number of languages with active/inactive marking. Levin and Rapaport Hovav (1995) explain the behavior of such verbs as examples of verbs of emission and show that they are part of a larger class of verbs expressing internally caused events.

In some languages it may be only the cross-linguistic semantic similarity that supports identifying inactive intransitives with unaccusative verbs on the one hand, and active intransitives with unergative verbs on the other. However, in other languages there are specific syntactic or morphological arguments for identifying the sole argument of an unaccusative as a direct object at some level. For example, Harris (1981, 1982) discusses Georgian evidence from number suppletion, preverb alternation, and number agreement, in which direct objects and the subject of unaccusatives pattern in the same way, and other evidence from syntax, where the subjects of transitives and unergatives pattern differently from the subjects of unaccusatives.

Different Semantic Bases

Mithun (1991) argues that active/inactive marking is determined on different semantic bases in different languages. For example, she states that Guaraní distinguishes between stative and event (nonstative) verbs, while Lakhota distinguishes agentive from nonagentive verbs. Mithun suggests that in central Pomo the distinction is based on an interaction of control and affectedness, much as O'Connor (1986, 1992) suggests for northern Pomo. Bowden (2001) has claimed that in Taba (East Makian), a language of the South Halmhera subgroup of the Austronesian family, agreement is determined on the basis of an interaction of two distinctions – one between humans and nonhumans and one between effector (much the same as agent) and noneffector. Much cross-linguistic work will be needed to sort out both terminological differences and potentially real differences between the criteria used in different languages to distinguish two types of intransitives for the purpose of marking.

Activity Theory

K Kuutti, University of Oulu, Oulu, Finland
R Engeström, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Cultural-historical activity theory (CHAT) is a school of thought concerning itself with the relation and interaction between humans and their material and social environment. Originally a psychological tradition, it has been expanded into a more general, multidisciplinary approach, which is used (besides in psychology) in semiotics, anthropology, sociology, cognitive science, linguistics, and design research. Thus, it would be more suitable to call it a framework, an approach, or a research program. From another perspective, CHAT is one of the few research traditions in human sciences originating in the former Soviet Union that have been able to gain acceptance in the Western research.

Historical Background

Cultural-historical activity theory, CHAT, originated in attempts by psychologists, as early as the 1920s, to establish a new, Marxist-based approach to psychology. The foundation of Activity Theory was laid by L. S. Vygotsky during the 1920s and early 1930s. (*see* **Vygotskii, Lev Semenovich (1896–1934)**.) His work was continued by A. N. Leont'ev and A. R. Lurija, who both developed his ideas further and began to use the term 'activity.' (A good historical review of that development can be found in Leont'ev, 1989.) For a Marxist psychologist, who favors a monistic explanation of human mental processes, the Cartesian mind-body dualism is unacceptable. Thus, the starting point of CHAT is that human thinking has both phylogenetically and ontogenetically emerged and developed in practical action and social interaction in the world; there is no separate mind that could be studied in isolation from these actions; significantly, the individual person is thus not a real unit of the analysis of mind. In any such analysis, the purposefulness of actions must be taken into account, and therefore it is necessary to include a minimal context that makes the actions meaningful for the acting subject. This context, typically a purposeful, social system of actions, is called an activity. Certain general principles within this framework include object orientation; mediation by culturally and historically formed artifacts (tools and signs); hierarchical structure of activity; and zone of proximal development.

Object Orientation

The most central feature of CHAT is that activities are oriented towards a specific object and that different objects separate activities from each other. In this tradition, the concept of object is complex and loaded. Activities emerge when human needs find a way to be fulfilled in the world. The object here is the entity or state of the world, the transformation of which will hopefully produce the desired outcome. An object has, thus, a double existence: it exists in the world as the material to be transformed by artifactual means and cooperative actions, but also as a projection on to the future—the outcome of the actions. The object is not exactly given beforehand, but it unfolds and concretizes in the interactions with the material and the conditions. Being a constantly reproduced purpose of a collective activity that motivates and defines the horizon of possible goals and actions, the 'sharedness' of the object is present only in social relations across time and space, as well as embodied in terms of history. Locally, the sharedness of an object is a process of social construction with divergent views and creative uses of cultural and interactional resources. Activities are thus often multivoiced, and none of the existing perspectives on the object can be defined as right—such a definition can only be given within an activity.

Mediation

The notion of tool mediation is one of the central features of CHAT. Actions are mediated by culturally and historically constituted artifacts, an artifact being defined as something that has been manufactured by a human. Thus, our relation with the world is shaped not only by our personal developmental history and experiences from various interactions, but also by the history of the broader culture we are part of. The world has been concretized in the shape of tools, symbols, and signs that we use in our activities. The world does not appear to us *as such*, uncontaminated, but as a culturally and historically determined object of previous activities. Humans project both these earlier meanings and those that have arisen from the fulfillment of current needs on to their objects; at the same time, they envision the potential results to be achieved. (*see* **Cognitive Technology**.) Language is an essential part of this toolkit, a tool of tools. According to CHAT, all mediation has both a language side and a material character: symbols and signs, and tools and instruments are all integral parts in the same mediation process. The basic mediational structure is depicted in Figure 1.

Figure 1 A model of the basic mediational structure. (S) subject, object (O), and medium (M) at the vertices of the triangle indicate the basic constraints of mind. The line S-O represents the 'natural,' (unmediated) functions; the line S-M-O represents the functions where interactions between subject and object are mediated by auxiliary means. St_n is the subject's state of knowledge at time n; O_{sm} is the object as represented via the medium; O_n, object at time n; St_{n+1}, emergent new state of the subject's knowledge at time n + 1 (Cole and Engeström, 1993: 5–7). Reprinted from Salomon (1993), *Distributed cognitions,* Figure 1.2, with permission from Cambridge University Press.

Figure 2 A model of an activity system (based on Engeström, 1987).The initial mediational triangle of individual actions is expanded to cover the social and cooperative dimension of an activity by adding a community sharing the same object and two new mediational relationships: social-cultural ('rules') between the subject and the community, and power/organizing ('division of labor') between the community and the shared object. The model is systemic in the sense that all elements have a relation with each other, but only the three main mediations are shown for the sake of clarity.

Thus the foundation of our actions is a continuous synthesis of two versions of the world: one directly given, the other culturally and historically mediated. Their synthesis enables us to plan our actions.

The Socio-Pragmatic Nature of the Sign

Activity Theory has paid much attention to semiotic mediation. Vygotsky's final work *Thought and Language* (1934) has contributed greatly to the understanding of human mental activity in socio-cultural terms, by assigning a crucial function to language as a psychological tool capable of mediating the development of the mind. Language as a tool calls for the use of artificial stimuli, that is, the use of culturally and historically construed sign systems. Signs serve to control the psyche and behavior of others and the Self, bringing to bear traces of social activities and social relations sedimented in language.

Vygotsky's socio-genetic approach to thought and language was developed originally in the research tradition of developmental psychology, aiming at understanding the child's mental growth. Later works of CHAT have continued with semiotic mediation and identity formation by focusing more on language use and utilizing notions such as the internal and external dialogicality of discourse. (*see* **Addressivity; Dialogism, Bakhtinian; Discourse, Foucauldian Approach; Discourse Processing.**) The interest is here in analyzing language from the viewpoint of sense-making, as it takes place within the contexts of the complex relationship between pragmatic activity and social processes. Sense-making is viewed as an active, culturally mediated process within and with which the external world is translated into a conceivable world and organized into objects of activities. Social change of language is explored with the help of developmental trends of sense-making through which new elements of meaning come into our social interests without leaving old meanings untouched.

Overall Structure of Activities

According to Leont'ev (1978), activities have a three-level hierarchical structure. Besides the activity level, which is a particular system of actions, and the action level itself, there is a third level, the lowest one, of operations. Operations are former actions that have become automated during personal development, and which are triggered within actions by specific conditions in the situation. Whereas in actions, there are always planning, execution, and control phases, operations are much more condensed, rapid, and smooth. To become skilled in something is to develop a collection of related operations. Operations are not, however, like conditioned reflexes: if the conditions do not fit, the operations return back to the action level.

In the tradition of the founders of CHAT, new forms for depicting activity have been elaborated. The most influential attempt to model an activity is due to Engeström. In his *Learning by expanding*, he aimed at defining a historically and concretely constituted system that has a timespan and internal transformations of its own. The model is presented in Figure 2.

In Figure 2, the model of individual action in Figure 1 has been complemented to depict the collective activity system. The model looks at the activity from the point of view of one actor, the subject, but the fact that subjects are constituted in communities is indicated by the point in the model labeled 'community.' The relations between the subject and the community are mediated, on the one hand, by the groups' full collection of 'tools' (mediating artifacts) and, on the other hand, by 'rules' that specify acceptable interactions between members of the community, and 'division of labor,' the continuously negotiated distribution of tasks, powers, and responsibilities among the participants of the activity system (Cole and Engeström, 1993: 7).

In an activity, the relation between individual actions and the outcome of the whole activity becomes mediated and indirect. Leont'ev (1978) explained the relation between individual actions and collective activity using an example of primitive hunters who, in order to catch a game, separate into two groups: the catchers and bush-beaters, where the latter scare the game in order to make them move towards the former. Against the background of the motive of the hunt—to catch the game to get food and clothing material—the individual actions of the bush-beaters appear to be irrational unless they are put into the larger system of the hunting activity.

Zone of Proximal Development

Activity systems are socially and institutionally composed entities exhibiting internal conflicts which develop through transformations. The characteristic feature of CHAT is the focus on such changes; it studies cognition, including language, as a dynamic, culture-specific, and historically changing phenomenon constituting activity systems. In this context, the zone of proximal development (ZPD) has became Vygotsky's most widely referenced notion. It concerns children's learning processes, and refers to

> the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers. (Vygotsky, 1978: 86)

Current activity theoretical studies extend from Vygotsky's dyadic pedagogical outline to potential horizons of different activities that will "mature tomorrow but are currently in an embryonic state." In the tradition of developmental work research, Vygotsky's ZPD indicates in outline the distance between present everyday actions and the historically new forms of the societal activity. In Engeström's model, contradictions in activity systems are "structural misfits within or between activities. The new forms of activity can be collectively generated as a solution to the double bind potentially embedded in everyday actions." (Engeström, 1987: 174). Contradictions may not be apparent or obvious, and they often appear as problems and disruptions in the flow of ordinary activities. In CHAT, new challenges of scientific concepts are also actively reflected in the ongoing research. Researchers in the areas of cognition and language studies are participating in the current development of discourse-based concepts.

The International Community

An international CHAT research community has been emerging, beginning from the late 1970s. In the early 1980s, there was a series of Northern European CHAT conferences on education; the first international CHAT conference was held in 1986 in Berlin, where the International Society for Cultural Research and Activity Theory (ISCRAT) was founded. This acronym was also the name used for a series of conferences: in Lahti, Finland, 1990; in Moscow, 1995; in Aarhus, Denmark, 1998; and in Amsterdam, 2002. A couple of these conferences have had their proceedings published as a selection of papers (Engeström *et al.*, 1999; Chaiklin *et al.*, 1998). In 2002, ISCRAT has joined forces with the Society of Socio-Cultural Studies (SSCS), resulting in a new society called International Society for Cultural and Activity Research (ISCAR), whose first joint world conference will be held in Seville, Spain, in 2005.

From 1994 on, the CHAT-oriented *Mind, Culture, and Activity. An International Journal* has been published by Lawrence Erlbaum.

Adamawa-Ubangi

J Bendor-Samuel, Summer Institute of Linguistics, High Wycombe, UK

© 2006 Elsevier Ltd. All rights reserved.

The languages grouped together as Adamawa-Ubangi belong to the Volta-Congo branch of the Niger-Congo family. These languages are spoken across central Africa in an area that stretches from northeastern Nigeria through northern Cameroon, southern Chad, the Central African Republic (CAR), and northern Zaire into southwestern Sudan.

The Speakers

In the absence of firm figures, the number of speakers of languages in this group can only be estimated at around eight to nine million people. Several languages with a million or more speakers belong to this group (e.g., Zande in CAR, Zaire, and Sudan; Ngbaka in North Zaire; and Gbaya in CAR and Cameroon).

Study of the Group

Little study of the languages in this group was undertaken before the 20th century. Westermann and Bryan (1952) treated them as individual units or clusters. Greenberg (1963) was the first to group them together as a branch of Niger-Congo. He used the name 'Adamawa-Eastern' for this group of languages. Samarin (1971) suggested the use of the name 'Ubangi' to replace 'Eastern.' Boyd (1989) has summarized recent studies on this language group, showing that for many of the languages there has been little detailed research. This is particularly true of the Adamawa languages. Knowledge of many of them is very sketchy.

Classification

The languages fall into two main groups – Adamawa and Ubangi. The Adamawa languages are found in northern Nigeria, Cameroon, and Chad, whereas the Ubangi languages are spoken in CAR, northern Zaire, and southwestern Sudan.

The Adamawa languages are divided into 16 groups: Waja (at least 6 languages), Leko (4 languages), Duru (18 languages), Mumuye (9 languages), Mbum (7 languages), Yungur (5 languages), Kam, Jen (2 languages), Longuda, Fali, Nimbari, Bua (9 languages), Kim, Day, Burak (6 languages), and Kwa.

Lexicostatistic studies show that the relationship among the groups is loose, but some of them can be grouped together so that two or perhaps three clusters emerge. The Leko, Duru, Mumuye, and Nimbari groups form a core of closely related languages. Another cluster comprises Mbum, Bua, Kim, and Day. Possibly a third cluster of Waja, Longuda, Yungur, and Jen can be formed.

The Ubangi languages show a much closer relationship to each other than do the Adamawa languages, and they fall into six main groups: Gbaya (4 languages), Banda, Ngbandi, Sere (6 languages), Ngbaka-Mba (9 languages), and Zande (5 languages).

Structural Features

Phonetics and Phonology

In Adamawa languages the set of initial consonants is much larger than the set of noninitial consonants, whereas in Ubangi languages there is little difference in size between the two sets of consonants. Most languages have either a five- or seven-vowel system.

The Leko, Duru, Mumuye, and Nimbari groups form a core of closely related languages. Another cluster comprises Mbum, Bua, Kim, and Day. Possibly a third cluster of Waja, Longuda, Yungur, and Jen can be formed.

The Ubangi languages show a much closer relationship to each other than do the Adamawa languages, and they fall into six main groups: Gbaya (4 languages), Banda, Ngbandi, Sere (6 languages), Ngbaka-Mba (9 languages), and Zande (5 languages).

Structural Features

Phonetics and Phonology

In Adamawa languages the set of initial consonants is much larger than the set of noninitial consonants, whereas in Ubangi languages there is little difference in size between the two sets of consonants. Most languages have either a five- or seven-vowel system.

Two, three, or four contrastive tones are found. Downstep is not common.

Grammar and Syntax

Noun class systems are not universal and are found mainly in the Adamawa languages. Some only comprise paired singular and plural suffixes without concord markers.

Verb systems usually contrast perfective and imperfective forms. Verbal extensions mark iteration, intensive, benefactive, and causative. Generally, inflectional morphemes are prefixed, and derivational morphemes are suffixed.

The predominant sentence word order is SVO. Negative markers occur clause final, and interrogative markers and words occur sentence final.

Adamczewski, Henri (b. 1929)

A-M Santin-Guettier, University of Le Mans, Le Mans, France
F Toupin, University of Tours, Tours, France

© 2006 Elsevier Ltd. All rights reserved.

Henri Adamczewski was born in France of Polish emigrants. As a child he already spoke three languages, Polish, Picard, and French, and it did not take him long to be fascinated by other languages as well, such as German, Russian, and Italian.

Adamczewski was a lecturer in, then a professor of, linguistics at the University of Paris 3, in the department of English studies, from 1970 to 1997.

In 1976 he defended his doctoral dissertation on the role of *be+-ing* in English grammar. The ideas he advanced did away with the traditional view of the 'progressive' or 'continuous' form and presented a novel approach in terms of the utterance-processing operations that reveal the discourse-implementing activity of the speaker.

For the last 30 years or so, the scope of his original concepts has been steadily extended, first to other fields of English grammar, then to a variety of other languages, irrespective of genealogical classification. The set of methods, concepts, and tenets underpinning the studies carried out by Adamczewski and by the linguists he trained is now referred to as Metaoperational Theory.

In 1995 Adamczewski turned to the question of child language acquisition, challenging the Generative views on the subject. Adamczewski has also been instrumental in the development of the didactic applications of theoretical linguistics in France. He is the author of two books presenting elements of his explicative grammar to French learners of English. He did not forget the educated layperson either, for whom two of his books are intended (one is in English: Adamczewski, 2002).

Adamczewski is considered one of the leading linguists in France and a pioneering figure in English linguistics, a field in which he is probably best known for his innovative views on *be+-ing* and on the auxiliary *do* in the context of the early 1970s. He has described the contrast between simple past or present sentences and *be+-ing* utterances in terms of structure (ternary vs. binary structure, the constituent [predicate]-*ing* being a preconstructed package applied to the grammatical subject); of orientation (right- vs. left-oriented utterances); and of pragmatic strategy (imparting new information vs. commenting on a state of affairs):

(1) *I leave tomorrow.*

(2) *I am leaving tomorrow.*

In (1) the speaker selects *tomorrow* instead of any other time marker available in the paradigm. In

Two, three, or four contrastive tones are found. Downstep is not common.

Adaptability in Human-Computer Interaction

J L Mey, University of Southern Denmark, Odense, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Introduction

In this article, two main themes will be touched upon: first, I will discuss the general topic of humans' adaptation to computers as tools, and conversely, how the computer tool can be adapted to human needs; and second, a particular instance of this adaptive process, in which both humans become (more) literate on and through the computer and computers are becoming more 'human,' will be discussed under the label of 'computer literacy.' In both cases, emphasis will be placed on the cognitive aspects of the problems, as embodied in the metaphors that are current in this particular discourse.

Adaptation and Adaptability

Adaptation

Earlier views on the computer as a tool (e.g., in human problem solving) have concentrated on the problem of *adaptation*: who or which is going to adapt to whom or which? (For a discussion of 'adaptability' vs. 'adaptivity,' where the latter is defined as a unilateral coercion on the human to conform to the patterns of behavior imposed by the computer, the former captures the necessity of letting the human decide to which degree, and to what purpose adaptation should be practiced, cf., Mey, 1998.)

Even though such efforts have their rationales in the context of computer modeling as it is usually understood, they do not touch upon the basic problem of adaptation, seen as a dialectic process of integrating two independent but interacting systems, the human and the computer (Mey and Gorayska, 1994). The case is analogous to that of perception; here, neither the senses nor the objects can be said, by themselves and unilaterally, to produce a sensation (e.g., of seeing). Perception is always perception of something, and it is always a perception by and in somebody. In the psychologist James J. Gibson's words, it is a "circular act of adjustment" (Gibson, 1979): "The activity of perception is not caused, nor is it an act of pure will" (Reed, 1988: 200).

An adaptability approach to computing thus endeavors to integrate two systems:

1. the human user, and
2. the computer tool.

In human-computer interaction, the human neither unilaterally 'acts' upon the computer, nor does the computer unilaterally prescribe the human some restricted form of activity. Rather, each system adapts to the other; their functional qualities, taken together, are what makes the use of the computer as a tool possible. In Gibsonian terms, tool making and tool using are tantamount to looking for and exploiting "affordances" (Gibson, 1979). To see this, consider the way our adaptation to, and interaction with, computers is characterized by our use of metaphors (*see* **Metaphor: Psychological Aspects**).

Computers and Metaphors

Like every other human activity, the use of computers has generated its own set of metaphors. We do our word processing using a 'mouse,' 'scroll' files up and down, 'chase' information on the Internet, get 'lost' in cyberspace, or trapped in the 'mazes' of the 'web'; and even if we have no idea what we are doing where in cyberspace, it can always be called 'surfing.'

(2) *tomorrow* belongs to the preconstructed predicate [*leaving tomorrow*], applied as a whole to the subject *I*, on whose situation the speaker comments.

Strongly opposing any analysis of *do* in terms of a 'dummy' auxiliary, he has demonstrated that whatever the context – emphatic, interrogative, or negative – *do* represents the linking operation of a subject and a predicate, insisting that English is probably the only language in the world that possesses an explicit marker of such an important operation.

Introduction

In this article, two main themes will be touched upon: first, I will discuss the general topic of humans' adaptation to computers as tools, and conversely, how the computer tool can be adapted to human needs; and second, a particular instance of this adaptive process, in which both humans become (more) literate on and through the computer and computers are becoming more 'human,' will be discussed under the label of 'computer literacy.' In both cases, emphasis will be placed on the cognitive aspects of the problems, as embodied in the metaphors that are current in this particular discourse.

Adaptation and Adaptability

Adaptation

Earlier views on the computer as a tool (e.g., in human problem solving) have concentrated on the problem of *adaptation*: who or which is going to adapt to whom or which? (For a discussion of 'adaptability' vs. 'adaptivity,' where the latter is defined as a unilateral coercion on the human to conform to the patterns of behavior imposed by the computer, the former captures the necessity of letting the human decide to which degree, and to what purpose adaptation should be practiced, cf., Mey, 1998.)

Even though such efforts have their rationales in the context of computer modeling as it is usually understood, they do not touch upon the basic problem of adaptation, seen as a dialectic process of integrating two independent but interacting systems, the human and the computer (Mey and Gorayska, 1994). The case is analogous to that of perception; here, neither the senses nor the objects can be said, by themselves and unilaterally, to produce a sensation (e.g., of seeing). Perception is always perception of something, and it is always a perception by and in somebody. In the psychologist James J. Gibson's words, it is a "circular act of adjustment" (Gibson, 1979): "The activity of perception is not caused, nor is it an act of pure will" (Reed, 1988: 200).

An adaptability approach to computing thus endeavors to integrate two systems:

1. the human user, and
2. the computer tool.

In human-computer interaction, the human neither unilaterally 'acts' upon the computer, nor does the computer unilaterally prescribe the human some restricted form of activity. Rather, each system adapts to the other; their functional qualities, taken together, are what makes the use of the computer as a tool possible. In Gibsonian terms, tool making and tool using are tantamount to looking for and exploiting "affordances" (Gibson, 1979). To see this, consider the way our adaptation to, and interaction with, computers is characterized by our use of metaphors (*see* **Metaphor: Psychological Aspects**).

Computers and Metaphors

Like every other human activity, the use of computers has generated its own set of metaphors. We do our word processing using a 'mouse,' 'scroll' files up and down, 'chase' information on the Internet, get 'lost' in cyberspace, or trapped in the 'mazes' of the 'web'; and even if we have no idea what we are doing where in cyberspace, it can always be called 'surfing.'

It's as if we were hanging out on the corners of our computational space – what one could call, using a novel metaphor, our 'cyber-hood,' our computerized neighborhood.

Among the various metaphors that currently characterize the computer and its use by humans, that of 'tool' has been one of the most pervasive. Just as tools help us execute certain activities better and faster, so too has the computer been considered a tool for performing certain operations (such as bookkeeping, accounting, tallying, registering, archiving, and so on) in a better, more efficient, and especially faster way. Among the attributes of this tool that have attracted most attention are, naturally, the ease with which it 'falls into' the human hand and routine; by extension, the computer is not even thought of as a tool any longer: enter the invisible, or 'transparent' tool (as I have called it; Mey, 1988), to be preferred over other, more visible and obtrusive kinds of instruments. The computer that adapts itself to the human user becomes an extension of the human body; conversely, the adaptable human user will treat the computer not just as any old tool, but rather as a crutch, a 'scaffolding' (in Bruner's terminology; Bruner, 1983), or even as a prosthesis, as we will see below (*see* **Scaffolding in Classroom Discourse**).

A Case in Point: The Computer as Prosthesis

It has been well known, ever since the pioneering work of people like Carroll (1991), that the tool we use to perform a particular task not only assists us in doing what we have to do, but also changes our understanding of the task itself and of a host of other things related to the task. It may change the very nature of the task altogether. For instance, to cite a classical case, the vacuum cleaner was originally introduced to alleviate and lessen a housekeeper's boring chores. In the end, it has increased the workload and made the work itself even more boring, because now it had to be performed more often and to a greater degree of perfection. The tool changes the task, and vice versa, in a never-ending "spiral" (Salomon, 1993).

With regard to computers, the tool has frequently been likened to a prosthesis. In the context of our discussion, this has had some profound effects. A prosthesis, one could say, is simply an augmentation of a human capability (either replacing a lost faculty or extending an existing one). But if we scratch this seemingly innocent surface, a host of hidden assumptions and unexpected problems turn up. First, there is the question of the augmentation itself: how far should we go, or be allowed to go, in the enhancing of the human sensory faculties? Using super-powered lenses and telecameras, we can spy upon the most intimate happenings in the lives of famous people like the late Princess Diana. But even though the majority of readers of the tabloid press would not be without their daily dose of lurid photojournalism, everybody agrees in condemning the excesses of the paparazzi when their need for media coverage directly or indirectly harms the celebrities they are pursuing, as it happened in the case of Princess Diana's death. "They are going too far," we hear people say. But what exactly is 'going too far' in what essentially is an adaptation of human goals and values to the possibilities of the tool? And how do we decide what is an acceptable limit for this adaptivity? On the one hand, more knowledge is more power; on the other, 'curiosity killed the cat' (and did irreparable damage to some notable humans and their progeny as well, as the case of Adam and Eve amply illustrates).

The Fragmented Body

The tool metaphor of the computer as a prosthesis carries with it yet another drawback. Since prostheses typically target one particular human capacity for augmentation, we come to think of our capacities as individually 'enhanceable.' There are two aspects to this enhancing: one, we consider only the individual agent, without taking his or her larger societal context into account; and two, we enhance single faculties in the individual, without taking into account the fact that these capacities form a unit, a human whole.

As to the first aspect, the societal character of our capacities, consider the 'paradox of success' that Kaptelinin and Kuutti (1999) have drawn attention to: what succeeds in one context may, by its very success, be expected to be a failure in another, seemingly similar environment. Thus, the very fact that, say, a decision-making computer tool has proven successful in the United States may warn us against trying to introduce it into a Japanese surrounding, where decisions among humans are made in ways that are very different from what is common practice in the U.S. (Kaptelinin and Kuutti, 1999: 152).

The other aspect relates to a currently popular notion of human capacities as being 'modularly replaceable.' Just as we are seeing the beginnings of 'surgical engineering,' in which techniques of replacement have substituted for old-fashioned operation and healing procedures, so we are witness to a trend toward substituting and augmenting not only parts of the body itself (such as is done in heart or kidney transplantation), but entire mental functions. A reasoning chip implanted in our brain relieves us from the headaches of going through the motions of filling in the trivial parts of a mathematical proof or a chain of syllogisms. A chip may replace a

person's worn-out or Alzheimer-affected memory capacities. In general, wetware can be replaced by more sturdy and robust electronic hardware, pre-wired to augment specific mental functions, and even tooled precisely to fit the needs of a particular individual. The potential for prosthetic innovations of this kind is virtually unlimited, up to the point where the whole person may end up being 'retooled' electronically (*see* **Cognitive Technology**).

The Effects of Adapting

Despite these problems, we are not exactly prepared to shut down our machines in the name of a return to basics, a kind of information-age Ludditism. We will have to live with the computer, even if our adaptation to it, as well as its role as an adaptive prosthesis, carries serious problems, generating side effects some of which were not intended. Here, it is useful to distinguish between primary and secondary effects. To take a well-known example, when Henry Ford wanted to put an automobile in everybody's front yard, the primary effect of this 'automotive revolution' was that people were able to travel farther and in ways not imagined before. But the secondary effects, not foreseen by Ford or anybody else at the time, included our adaptation to this new transportation device: our mind-set changed, the automobile becoming our premier status symbol, our 'escape on wheels,' for some even serving as an extra bedroom. In due course, these secondary effects (including the need to build more and more highways, in the process destroying entire rural and urban environments in the name of transportation, creating a new, 'suburban' life style for millions of people, and so on and so forth) were much more important than the simple primary effects in regard to our modes of transportation. The innovative tool re-creates that which it was only supposed to renew: the prosthetic tail wags the human dog.

Another problem with the prosthesis metaphor, when applied to the computer, is that of augmentation. The prosthetic tool, be it a crutch or a pair of binoculars, augments our motor or visual capacities. The notion of augmenting a human faculty presupposes the existence of something which is not augmented, or 'natural.' The trouble with humans, however, is that 'natural' behavior is a fiction; while we do have certain 'innate' functions (the faculty of speech, the ability to walk upright, and so on), these functions cannot be put to work 'naturally' unless we 'initialize' them, break them in socially and culturally. And in order to do this properly, we need tools. In particular, in any learning situation, we need what Bruner called a 'scaffolding': a total learning environment where the learner is gradually introduced to the next higher level of competency, all the way relying on the availability of physical and mental 'crutches'. And the more we enhance our human, culturally bound and socially developed functions, the less we rely on those crutches as external prostheses; we internalize the tools by making them part of ourselves, adapting and incorporating them, as it were, to the point where they are both 'invisible' and indispensable.

As an illustration, I will discuss the case of the word processor, thus leading into the second part of this article, which deals with the problems involved in computer literacy.

Computer Literacy

The Word Processor

A word processor is basically a tool for enhanced writing. Starting from the early, primitive off- and online text editors (such as RUNOFF or EDDY), modern word processors (such as the latest editions of Microsoft Word or WordPerfect) are highly sophisticated devices that not only help you write, but actually strive to improve your writing – and not just physically or orthographically. Text editors, for instance, will tell you that a sentence is ill formed or too long, or that a particular concept has not been properly introduced yet.

Computerized functions such as these may facilitate the ways in which we produce texts; on the other hand, the texts we produce are in many ways rather different from those that originated in a noncomputerized environment. Here, I'm not talking only about the outer appearances of a document (by which a draft may look like a final version of an article, and be judged on that count), but rather about the ways we practice formulating our ideas.

For instance, if we know that what we write may be disseminated across an international network, or abstracted in a database that is used by people from different walks of life and contrasting ethnic and cultural backgrounds, we will try to express ourselves in some kind of 'basic conceptualese,' shunning the use of metaphors and idiomatic expressions, thus sacrificing style to retrievability of information. As Oracle's Kelly Wical observed, such automated indexing of documents "will encourage people to write plainly, without metaphors . . . that might confuse search engines. After all, everyone wants people to find what they have written" (Wical, 1996; see also Gorayska, Marsh and Mey, 1999: 105 *ff.*).

In the following, I will examine some of these effects, and inquire into their desirability and/or inevitability.

Why Computer Literacy?

If literacy (no matter how we interpret this term) has to do with people's capacities for handling 'letters' (Latin: *literae*), then one may ask: What's so special about the computer that we need to define a special concept called 'computer literacy'? After all, people have been using the notion of literacy for ages, and there has never been a need to define a special kind of literacy for a particular tool of writing, such as a chisel, brush, or pen. Whereas 'penmanship' has become a synonym of 'high literacy' (no longer necessarily exercised by means of a pen), nobody has ever felt the need to define 'typewriter literacy' in terms other than in number of words per minute: a good ('literate,' if you want) typist can do at least 100 words per minute without committing too many errors, whereas a beginner or 'illiterate' person only can do 30 or 40 and will have to use a lot of time correcting his or her mistakes. In other words, there must be a difference, but what is it?

Writer and Tool

What makes a difference is in the relationship of the writer to his or her instrument: chisel and hammer, stylus and wax, quill and parchment, pen and paper, keyboard and screen. This relationship has not always been simple and straightforward; in particular, it has been known to influence the very way people write. The ancient Greek scribes who performed their craft in stone didn't bother to drag all their utensils back to the beginning of the line they just had finished: instead, they let the new line begin where the old one had stopped, only one level lower; thus, the script called *boustrophedon* (literally: 'the way the [plowing] oxen turn') came into being, with lines alternating in their direction of writing/reading. The medieval monks who wrote on parchment often tried to 'recycle' this precious and hard-to-get material by erasing earlier scripts and overwrite the deleted text, a technique known by the name of *palimpsest*. (By an irony of history, in due course the deleted text often turned out to be more valuable than the overwritten one. Many of the sources for our editions of the classical authors are due to the monks' parsimonious writing techniques.)

Undoubtedly, the invention of wood (later lead) letter type contributed greatly to the dissemination of written literature; yet, the effects on the scribe were never a matter of reflection. Much later, when the typewriter got naturally to be used for the purposes of office work, personal letters and literary 'works of art' still had to be composed by hand, if they were to be of any value. Even in a more practically oriented domain such as that of journalism, it is a known fact that the formidable Count Della Torre, in life chief editor of the Vatican daily *Osservatore Romano*, forbade the use of typewriters in his offices as late as 1948. His journalists had to write all copy by hand and then give it to a typist or typesetter.

The interaction between writer and tool changed dramatically with the advent of the computer. Not only is this writing instrument more perfect than any of its predecessors, but in addition it possesses a great number of qualities enabling people to approach their writing tasks in a different way. Accordingly, 'computer literacy' can be defined as: knowing how to exploit the various new uses to which the 'computer interface' between humans and letters can be put. Let's consider some of these uses.

How (Not) to Use a Computer

Here, I will not discuss the more specialized functions that computer writing has inherited from earlier technologies, merely perfecting but not changing them: bookkeeping and accounting (cf., the use of so-called 'spread sheets'), tabulating, making concordances, automated correspondence, and other office work (e.g., the automatic reminders one gets from one's credit card company or the local utilities services). The truly revolutionary aspect of computer literacy is in the effect it has on the writing process itself, that which earlier was thought of by some as sacrosanct, immune to any kind of mechanical implementation.

One could say that a truly 'computer literate' person is one who composes his or her literary production directly on the computer, without any interference except from the interface itself. This is a bit like composing directly on the piano, except that the keyboard there normally does not retain what has been played on it. In contrast, the conserving function of the computer is precisely what enables writers to enter into a totally new relationship with their tool.

Earlier work, being dependent on the paper medium, had to be meticulously corrected in the text itself, often with great problems of legibility and understanding (scratching or crossing out, 'whiting out,' overwriting, writing in between the lines and in the margins, cutting and pasting, and so on, with multiple versions often canceling out one another, or at least making perhaps better original lines impossible to retrieve). However, the computer allows the text producer to maintain near-complete independence of the material side of writing.

Paper has always been said to be 'patient' in that it did not protest against whatever the author put down on it, suffering great works of art and utterly trivial composition alike to be entered on its impartial surface. In comparison, the patience that the computer

exhibits is not just an inherent quality of the tool: it is transferred to, and located within, the computer 'literate' who knows that Pilate's age-old adage *Quod scripsi, scripsi,* "What I have written, I have written" (John, 19: 22) has been rendered null and void by this new medium. Here, it doesn't matter what is written, for everything can always be reformulated, corrected, transformed, and recycled at the touch of a keystroke or using a few specialized commands. In extreme cases, we even may see the computer generate near-automatic writing (in the sense of the surrealists), with fingers racing across the keyboard and authors failing to realize what's driving them on. Subsequently, the author who checks and goes over the results may often marvel at the 'inventions' that he or she has been guilty of producing, almost without being aware of the process by which they happened.

Perspectives and Dangers

I will conclude this entry by pointing to some of the perspectives that manifest themselves in a considered approach to the problem of adapting to/from the computer/human, especially as they appear in the context of computer literacy. In addition, I will say a few words about the possible dangers involved in the headlong embrace of new technologies (and their implied mental representations and ideologies) just because they are new. First, there is that age-old dilemma (going all the way back to Plato): Is the human just a kind of idealized entity coupled to a material reality ('a mental rider on a material beast of burden')? Or do we conceive of the union of the two in different ways, now that we have better metaphors to deal with these questions (especially the vexing problem of 'which is master': mind over matter or the other way around)?

Mind and Body Conceiving of the computer as a prosthesis may seem to finally resolve that ancient dichotomy: the mind-body split. If anything in the mind can be reproduced on a computer, then we don't need the body at all. Or, vice versa, if the computerized body can take over all our mental functions, why then do we have to deal with a mind?

There are indeed tendencies afoot that seem to advocate this kind of thinking. Some years ago, a book by Andy Clark (1997, frontispiece) proudly announced, in its subtitle, the ability to "put brain, body, and world together again". However, this synthesis is performed strictly on the basis of a computer-as-prosthesis informed philosophy: one describes the mental functions as (if need be, computerized) modules, united under a common ordering principle or joined loosely in some kind of mental republic, a 'society of mind' à la Minsky (1986), where the different mental functions, conceived of as semiindependent but jointly organized modules, cooperate to form an organized, governing whole.

In Clark's model, the emphasis is on the brain, not the mind, the latter being characterized as a "grab-bag of inner agencies." The "central executive in the brain – the real boss who organizes and integrates the activities" is said to be "gone." Also "[g]one is the neat boundary between the thinker (the bodiless intellectual engine), and the thinker's world." No wonder, then, that replacing this "comfortable image" puts us in front of a number of "puzzling (dare I say metaphysical?) questions" (Clark, 1997: 220–221). Leaving those questions aside in our context, let me briefly explore some possible practical consequences of this 'dementalization,' when seen as involving a decentralization of the individual's capacities.

Mind, Creativity, and Control While the acquisition of computer literacy as a condition for employment does not create much of a difference as compared with earlier situations (except for the extra cost and training it involves), the use of the computer in creative contexts represents a true breakthrough in the relationship of humans to their work, especially as regards their ways of creative production and reproduction. The interesting question here is not what the computer does to our hands, but in what ways it affects our mental ability to shape and reshape, to work out a thought, and then abandon it (but not entirely!). It is also in how it allows us to come back to earlier thoughts and scraps of insights that were jotted down in the creative trance, as it were – perhaps recombining these *disiecta membra* with other pieces of thought, all available at the drop of a keystroke. This qualitative change of our relationship with our creative tools is the true computer revolution; it defines 'computer literacy' as being qualitatively different from earlier, more primitive, creative and cognitive technologies.

The imminent danger of the spread of computer literacy is, of course, that any Tom, Dick or Emma who can handle a keyboard may consider themselves to be geniuses of writing, thus offsetting the positive effect of increased literacy through this reduction of the computer tool to an instrument of and for the inane and mindless. More importantly though, the danger exists that users, because of the apparent naturalness of their relationship to the computer, start considering themselves as natural extensions of the machine, as human tools. Being 'wired' becomes thus more than a facile metaphor: one has to be plugged into some network, both metaphorically and electronically, to be able to survive in today's 'wired' society. The wireless person just 'isn't there.'

To see this, consider the way most people are wired into the mass media of communication: their lives and thoughts are dictated by the media. Whoever doesn't plug into this immense network of 'infotainment' (information and entertainment), is 'out,' is an 'outsider,' in the strictest sense of the word; outside of the talk of the day at the workplace, outside of the discussions in the press, outside of the newscasts and television reports on current scandals and shootings. An 'insider,' on the other hand, does not (and cannot) realize to what extent the simple presence of thought and feelings, otherwise considered as 'naturally' arising within the mind, is due to his or her 'wiredness,' his or her connection to the networks. It takes the accidental 'black screen' (or some other temporary media deprivation) to make one fathom the depths of one's dependency, the extent of one's being 'hooked up' to the infotainment universe (and as a result, being 'hooked on,' not just 'wired into,' that universe).

'Big Brother' and the Mind's 'Holding Company'
A final issue is of a subtler, less technical, and for that reason all the more threatening, nature; it has to do with the nature of the mental prosthesis that the computer represents. The computer's special features (programs and functions that are distributed throughout the hardware rather than being encapsulated in neat, identifiable blocks of instructions, routines being divided into subroutines to be used independently and/or recursively, and so on) have led some of us to think of the brain as a similarly organized, distributed architecture (like Minsky's "society of mind," mentioned above). In particular, the currently popular 'connectionist' view of mental processing is based on this analogy; the prosthesis metaphor, if applied within this frame of thinking, transforms the individual mental features and functions into a set of independent, yet connected components (what Clark irreverently called a "grab-bag of inner agencies"; 1997: 221). The question is, and the problem remains, how to orchestrate all those brainy agencies into some kind of mental unit(y). For all practical purposes, one could replace the media outlets by some central instrument, have it wired directly into people's heads, and bingo, we're in business: the wired society becomes a frightening reality, with 'Big Brother' embodied in a central 'Holding Company,' a monster computer, controlling and directing our entire lives (cf. Big Brother and the Holding Company, 1968).

One frequently hears computer users employ expressions such as, "The computer is in a bad mood today" or "The computer doesn't want to cooperate"; one sees irritated users kick their machines, pound their keyboards, or scream at their screens, accusing these devices of lack of cooperation. Such expressions, when they are not caused by either the user's poor computer literacy, or by a particular hardware or software deficiency, may reflect either a lack of critical awareness of the computer's properties as an auxiliary tool, or a failure to distinguish between the respective roles of the partners in human-computer interaction and cooperation. The future of human computer interaction lies in the humanizing of the tool, not in the humans' becoming more tool-oriented and tool-like. And as to adaptation and adaptability, I repeat what I said earlier: the computer tail should never be allowed to wag the user dog.

Addressivity

G S Morson, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

'Addressivity' (*obrashchennost'*) is a term coined by the Russian scholar Mikhail Bakhtin as part of his critique of traditional linguistics. It figures as well in the thinking of Bakhtin's colleague, Valentin Voloshinov, and it is helpful in understanding the approach to language and the psyche taken by Lev Vygotsky (*see* **Voloshinov, V. N. (ca. 1884/5–1936); Vygotskii, Lev Semenovich (1896–1934)**).

Bakhtin's work on language is best understood as part of his more general project to rethink the basis of the humanities and social sciences. Initially trained as a literary scholar, Bakhtin sought to reconceive the nature of ethics, psychology, literature, and language in such a way that choice, unpredictability, and open time were properly acknowledged. His work is suffused with the sense that the study of culture cannot be a science in the hard sense, a view that sets him apart not only from his Marxist contemporaries but also from numerous schools since the 17th century. Because Bakhtin believed that human thought takes place primarily in the form of inner speech, a new understanding of language proved essential to his larger project of humanizing the 'human sciences.'

Bakhtin reacted to the beginnings of formalist and structuralist linguistics, which he understood as methods of understanding human speech as an instantiation of rules. In this model, the linguist studies the rules, *langue*, and regards individual speech acts, *parole*, as entirely explicable in terms of the rules (*see* **Principles and Rules; Saussure, Ferdinand (-Mongin) de (1857–1913)**). This model and its attendant assumptions seemed to Bakhtin to exclude not only all that we think of as pragmatics and the social aspects of language but also everything that is truly creative in any dialogue between real people. Bakhtin wanted to formulate an alternative model that treated language, thought, and action as capable of genuine 'surprisingness' (*see* **Conspicuity**).

To this end, Bakhtin distinguished between sentence and utterance. The sentence is a unit of language understood as structuralists do. It does not take place at any specific point in time, and so is repeatable; the same sentence may be spoken on different occasions. The utterance, by contrast, is a specific act of speech that someone says to someone else on a specific occasion, and its meaning depends in part on the occasion. Each occasion is different, and so utterances are never repeatable. The utterance is a historical event and is part of a dialogue. Sentences provide resources for an utterance, but the utterance requires more than the sentence. Linguistics properly conceived should deal with utterances as well as sentences, but so long as language is understood in terms of sentences, we should call the discipline that studies utterances 'metalinguistics.'

What utterances contain that sentences do not is addressivity. Utterances are constituted by the fact that they are part of a specific dialogic exchange. Addressivity denotes all those aspects of the utterance that make it dialogic in the deepest sense (*see* **Dialogism, Bakhtinian**). Sentences contain only the potential to mean something, but utterances actually do mean something. In Bakhtin's terms, sentences have meaning (in Russian, *znachenie*) in the sense of dictionary-and-grammar meaning, but utterances have *smysl* (roughly, sense, or meaning in a real context).

One cannot solve the problem of context by writing a grammar for it. Although one can say many general things about context, no grammar of context could ever fully specify it, because context is as various as human purposes, which are irreducible to a set of rules. No matter how many helpful rules one may devise, there will always be a 'surplus' (*izbytok*). Bakhtin uses the same term, 'surplus,' to describe that aspect of human beings that is left over after all

Abstract:

Adaptation, in a computer context, is a two-way street: humans adapt to the computer, and computers are adapted to human needs. The two sides of the process are not to be seen as a simple reversal of direction, however; the need to prioritize the human in relation to the computer, weights the need for adaptable computers on human terms stronger than the need for computer-adapted humans. The thoughts developed on this general subject are then applied to the case of what is often called 'computer literacy,' currently one of the most important realizations of computerized technology, in particular as to its cognitive aspects.

Biography:

Jacob L Mey (b. 1926) is Professor Emeritus of Linguistics at the University of Southern Denmark. Previous appointments include the University of Oslo, Norway; the University of Texas at Austin; Georgetown University, Washington, D.C.; Yale University, New Haven, CT; Tsukuba University, Japan; Northwestern University, Evanston, IL.; City University of Hong Kong; Goethe University, Frankfurt am Main; Universidade Estadual de Campinas, S.P., Brazil; Universidade de Brasília, Brasília, DF; the University of Haifa and Haifa Technion, Israel; as well as numerous other institutions of research and higher learning.

Jacob Mey's research interests concern all areas of pragmatics, with an emphasis on the social aspects of language use, the pragmatic impact of computer technologies, and the pragmatic use of literary devices. Among his publications in these areas are *Pragmalinguistics: theory and practice* (The Hague: Mouton, 1979); *Whose language? A study in linguistic pragmatics* (Amsterdam & Philadelphia: Benjamins, 1985), *Pragmatics: an introduction* (Oxford & Boston: Blackwell, 1993; second revised edition, 2001). This book has been translated into Japanese and Korean; a Chinese translation is about to appear (2002). His most recent publication is *As Vozes da Sociedade* (*The voices of society*; in Portuguese) Campinas, S.P.: Mercado de Letras, 2002).

As to the computer-related aspects of pragmatics, a recent development is a new field, Cognitive Technology (CT), which he is among the first to have developed. He has written and edited numerous articles and books in the area, co-organized several international conferences, and founded (together with Barbara Gorayska) the *International Journal of Cognition and Technology* (Amsterdam: Benjamins, 2002). The main interest of CT is to study the effects of the computer on the human mind, and vice versa, how the mind determines the uses we make of the computer as a tool.

Among Jacob Mey's other main interests are the theory of literature and poetics. These interests have recently culminated (following many earlier articles) in his book *When voices clash: a study in literary pragmatics* (Berlin: Mouton de Gruyter, 2000).

Jacob Mey is founder (with Hartmut Haberland) and chief editor of the monthly *Journal of Pragmatics* (Oxford: Elsevier Science). He also edits *RASK: International Journal of Languages and Linguistics* for Odense University Press. Among his other edited volumes are two readers on Cognitive Technology (1996, 1999), and the 1100-page *Concise encyclopedia of pragmatics* (1998), all published by Elsevier Science.

Jacob Mey holds an honorary Dr. Phil. degree from the University of Zaragoza, Spain. He is a member of various professional organizations, such as the Linguistic Society of America, the Copenhagen Linguistic Circle, and the International Pragmatics Association (of which he is a member of the consultative board). He is Editor or Member of the advisory board of a number of series and journals, such as *Pragmatics and Beyond* (Amsterdam), *Anthropological Linguistics* (Berlin), *Discourse and Society; Text; Language and Literature* (Liverpool); *Miscelánea* (Zaragoza); *Psyke og Logos* (Copenhagen); *Sémantique et Pragmatique* (Orléans), *Cadernos de Linguagem e Sociedade* (Brasília) and others. In 1998, he was elected to the office of vice-president of the newly founded Society for Cognitive Technology. Jacob Mey has been married to Inger Mey since 1965, and has six children. He loves music, the outdoors, and animals, especially cats. He hates bad weather, pessimists, and bureaucrats. Since his retirement in 1996, he spends much of his time in Austin, TX, where his wife is pursuing a Ph.D. degree in anthropology.

Addressivity

G S Morson, Northwestern University, Evanston, IL, USA

'Addressivity' (*obrashchennost'*) is a term coined by the Russian scholar Mikhail Bakhtin as part of his critique of traditional linguistics. It figures as well in the thinking of Bakhtin's colleague, Valentin Voloshinov, and it is helpful in understanding the approach to language and the psyche taken by Lev Vygotsky (*see* **Voloshinov, V. N. (ca. 1884/5–1936); Vygotskii, Lev Semenovich (1896–1934)**).

Bakhtin's work on language is best understood as part of his more general project to rethink the basis of the humanities and social sciences. Initially trained as a literary scholar, Bakhtin sought to reconceive the nature of ethics, psychology, literature, and language in such a way that choice, unpredictability, and open time were properly acknowledged. His work is suffused with the sense that the study of culture cannot be a science in the hard sense, a view that sets him apart not only from his Marxist contemporaries but also from numerous schools since the 17th century. Because Bakhtin believed that human thought takes place primarily in the form of inner speech, a new understanding of language proved essential to his larger project of humanizing the 'human sciences.'

Bakhtin reacted to the beginnings of formalist and structuralist linguistics, which he understood as methods of understanding human speech as an instantiation of rules. In this model, the linguist studies the rules, *langue*, and regards individual speech acts, *parole*, as entirely explicable in terms of the rules (*see* **Principles and Rules; Saussure, Ferdinand (-Mongin) de (1857–1913)**). This model and its attendant assumptions seemed to Bakhtin to exclude not only all that we think of as pragmatics and the social aspects of language but also everything that is truly creative in any dialogue between real people. Bakhtin wanted to formulate an alternative model that treated language, thought, and action as capable of genuine 'surprisingness' (*see* **Conspicuity**).

To this end, Bakhtin distinguished between sentence and utterance. The sentence is a unit of language understood as structuralists do. It does not take place at any specific point in time, and so is repeatable; the same sentence may be spoken on different occasions. The utterance, by contrast, is a specific act of speech that someone says to someone else on a specific occasion, and its meaning depends in part on the occasion. Each occasion is different, and so utterances are never repeatable. The utterance is a historical event and is part of a dialogue. Sentences provide resources for an utterance, but the utterance requires more than the sentence. Linguistics properly conceived should deal with utterances as well as sentences, but so long as language is understood in terms of sentences, we should call the discipline that studies utterances 'metalinguistics.'

What utterances contain that sentences do not is addressivity. Utterances are constituted by the fact that they are part of a specific dialogic exchange. Addressivity denotes all those aspects of the utterance that make it dialogic in the deepest sense (*see* **Dialogism, Bakhtinian**). Sentences contain only the potential to mean something, but utterances actually do mean something. In Bakhtin's terms, sentences have meaning (in Russian, *znachenie*) in the sense of dictionary-and-grammar meaning, but utterances have *smysl* (roughly, sense, or meaning in a real context).

One cannot solve the problem of context by writing a grammar for it. Although one can say many general things about context, no grammar of context could ever fully specify it, because context is as various as human purposes, which are irreducible to a set of rules. No matter how many helpful rules one may devise, there will always be a 'surplus' (*izbytok*). Bakhtin uses the same term, 'surplus,' to describe that aspect of human beings that is left over after all

conceivable causal explanations have been applied. One's true selfhood begins where all possible categories and causes have been exhausted. In selfhood, the 'surplus' constitutes our humanness, and in utterances it constitutes the manifestation of humanness in language.

Addressivity involves everything that takes the resources of speech – dictionary meanings, grammar, syntax, rules of context – and turns them into an utterance. In practice, Bakhtin's work involved specifying features of context that were left out by structural linguistics, and so it overlaps strongly with pragmatics. It would be possible to absorb many of Bakhtin's insights into pragmatics without accepting his view of humanness, indeterminism, and the surplus (*see* **Pragmatics: Overview; Structuralism**).

Consider, for instance, the telegraphic model of language in which a speaker, intending to convey a message, instantiates the rules of language to produce a sentence. In that model, the message is then sent out through a medium to a listener, who decodes the sentence and so recuperates the original meaning. Speaking is encoding, and listening is subsequent decoding. The first problem with this model, in Bakhtin's view, is that nothing in this description would change if the listener were asleep, absent, or entirely different. But in real exchanges, the listener does not passively decode. Understanding is an active process in which the listener not only decodes, but also imagines how the utterance is meant to affect him or her, how it responds to past and potential utterances, and how third parties might respond. With all these factors in mind, the listener prepares a response that is revised as the utterance is being heard. Understanding is personal, processual, and active. Because every speaker counts on understanding of an active sort, the listener shapes the utterance from the outset. Speakers formulate their utterances with a specific listener or kind of listener in mind. This anticipation of a listener, which in ordinary speech is often guided by responses we sense **as** we are speaking, alters the tone, choice of words, and style of each utterance as a work in process.

Except in the purely physiological sense, each utterance is a co-creation of speaker and listener. It is essentially joint property. Bakhtin offers a series of examples, drawn from Dostoevsky's novels, of utterances whose whole point and stylistic shape would be missed without considering addressivity. In 'the word with a loophole,' for instance, the speaker deliberately exaggerates a self-characterization so that, if the response is undesired, the utterance allows him to pretend after the fact that it was parodic or unserious. The utterance builds into itself future utterances to more than one possible response.

Such utterances are not only common in daily speech, but also figure in our psyche. Because thought largely consists of inner dialogues, our minds are composed of the listeners that inhabit us – our parents or other figures whose responses count for us. We address them when we think, and so our very thought is shaped by imagined anticipated responses. We justify ourselves, or guide our thoughts by what significant internalized others might say. We grow and change as we absorb new listeners or learn to address old ones differently.

Within and without, we live dialogically. Addressivity, the dialogue of inner and outer speech, involves not only the 'second person' (the listener) but also what Bakhtin calls the 'third person.' In different studies, the term 'third person' has two distinct meanings, both of which are essential to addressivity. Sometimes the third person refers to all those who have already spoken about the topic in question. No one speaks about anything as if he or she were Adam, the first to break the silence of the universe. Every topic has been 'already spoken about' and the words referring to this topic implicitly 'remember' the earlier things said about it and the contexts in which they were said. It is as if words have glue attaching to them the evaluations and meanings of earlier speakers. Thus, when we speak, we implicitly take a stand in relation to those earlier speakers, and our words may be spoken as if with quotation marks, at a distance, with various tones indicating qualification. Some words come already 'overpopulated' with earlier utterances. Our speech therefore contains implicit elements of reported speech (direct or indirect discourse) in which the framing utterance takes a stance with respect to the framed one. Such effects may not be visible in the words when viewed as parts of a sentence, but they are nevertheless keenly sensed by speaker and listener. We are in dialogue with our predecessors, and addressivity refers to this historical aspect of utterances as well as to the present speaker-listener relationship. Whether we are considering the second or third person in addressivity, the utterance is shaped by others.

A second sense of 'third person' refers to what Bakhtin calls the 'superaddressee' (*nadadresat*). We never turn over our whole selves to a listener, because we cannot count on perfect understanding. Each utterance is partially constituted by the projection of an ideal listener, an invisibly present third person who would understand perfectly. We sometimes make the superaddressee visible when, in talking with one person, we gesture, as if to say, 'would you just listen to him!' But visible or invisible, the superaddressee is part of every utterance. The superaddressee may be personified as God or imagined as the voice of history,

but strictly speaking it is a constitutive factor of the utterance itself. We implicitly address this perfect listener as well as the real one before us. The super-addressee also figures in our inner speech, where again it may be personified.

The idea of addressivity allows Bakhtin to analyze a series of utterances that may look linguistically or stylistically simple but that are in fact complex when we consider them as part of a dialogue. Imagine a conversation in which one speaker's voice has been omitted but its intense effects have left their mark on the other speaker's utterance: some speech is shaped as if that process had taken place, as if it were one part of a tense exchange. Such speech takes 'sidelong glances' at the other's potential answer and may almost seem to cringe in anticipation of a response. Utterances may be 'double-voiced,' so that they seem to emerge from two speech centers simultaneously, each commenting on the other and addressing themselves to a third party. In extreme cases, such utterances may bespeak psychological disturbance, as in Dostoevsky. But double-voicedness also appears in simple form in parody. A vast variety of discourses become visible when we consider them from the perspective of addressivity (*see* **Narrativity and Voice**).

In contrast to such movements as 'reader reception' theory, Bakhtin sees the listener's response as active, not just after an utterance is made, but also while it is being made. Bakhtin is attentive to the formulation of an utterance as a shifting process. An utterance may change in the course of being said – in response to others, to circumstances, or even to the sound of itself. We are ourselves one listener of our speech acts, impersonating potential others. Bakhtin regards a culture's forms of addressivity as constantly changing in response to circumstances and the creativity of individuals. Some typical forms of addressivity may coalesce into speech genres, and to learn a language involves learning those genres. Speech genres differ from language to language and change over time (*see* **Genre and Genre Analysis**).

For Bakhtin, the idea that utterances may change as they are being made suggests that addressivity presumes a speaker truly 'present' and ethically 'responsible' (literally 'answerable' in the original Russian) for what he says and a listener present and responsible for how he listens. As speakers and listeners, we choose and may be held accountable for our choices. Nothing is already made or entirely explicable in terms of pre-given codes or prior causes. Thus, the concept of addressivity is closely connected with Bakhtin's insistence that ethics can never be a mere instantiation of rules; each situation requires real presence and judgment. In what we do as in what we say, we really accomplish something never done before. Or as Bakhtin liked to say, there is no 'alibi.' These broad implications of addressivity explain why its pragmatic aspects belong to Bakhtin's project of altering 'the human sciences.' He describes human beings as social to the core because even in our psyche we think by dialogue. Conversely, he describes society and language as possessing both surprisingness resulting from the creative aspects of each dialogue and ethical significance resulting from our answerability for each utterance with addressivity.

Adelung, Johann Christoph (1732–1806)

K-Å Forsgren, Umeå Universitet, Umeå, Sweden

© 2006 Elsevier Ltd. All rights reserved.

German Librarian, Lexicographer and Grammarian

Johann Christoph Adelung (see **Figure 1**) was born on the 8th of August 1732 at Spantekow, near Anklam, Pomerania, as the son of a vicar. After going to school in Anklam he studied theology from 1752 to 1756 in Halle. He then worked as a senior high school teacher in Erfurt (1758–1762). From this position, however, Adelung had to resign due to a confessional controversy. For the period 1762–1765 no certain details of his whereabouts are known; he was possibly a librarian at Gotha. The following years he spent at Leipzig, and, being unemployed, made a living as a translator and as an editor of various publications. In 1787, he was appointed head librarian of the electoral library of Dresden, whose organization he improved and developed. Adelung remained in Dresden until his death on the 10th of September 1806.

Figure 1 Portrait of Johann Christoph Adelung. Reproduced from Martin-Luther-Universitat, Halle-Wittenberg, with permission.

Adelung's work as a translator and as an editor of some 10 magazines and periodicals covered various fields, above all, history but also natural sciences, education, geography, and cultural history. This and, of course, his profession as a librarian gave him a very broad survey of the general state of the art of his time. In 1766, Adelung was commissioned by the publisher Breitkopf to continue the work on an extensive dictionary of the German language (German, Standard), which had only just been started by J. C. Gottsched. The five volumes with the title *Versuch eines vollständigen Wörterbuchs der hochdeutschen Mundart* were published between 1774 and 1786, and a second revised edition was published between 1793 and 1802 (*Grammatisch-kritisches Wörterbuch der hochdeutschen Mundart*), at the time the most extensive dictionary of the German language and its dialects. Henceforth the German language was Adelung's main field of interest as a scholar. Another commission by the Prussian Prime Minister, Baron von Zedlitz, was the starting point of his activities as a grammarian and resulted in the *Deutsche Grammatik* of 1781, followed by a simplified version intended for elementary schools that was also published in 1781. Very soon an extensive, explanatory version in two volumes (*Umständliches Lehrgebäude* and *Grundsätze der deutschen Orthographie,* 1782) of his school grammar appeared. Two previous publications on the history and origin of language (*Über die Geschichte der deutschen Sprache, 1780; Über den Ursprung der Sprache*, 1781) were included in the *Umständliches Lehrgebäude*. The latter also contains his theory of word formation, which he regarded as a historical process (etymology). In the periodical *Deutsches Magazin*, which appeared in two annual

German Librarian, Lexicographer and Grammarian

Johann Christoph Adelung (see Figure 1) was born on the 8th of August 1732 at Spantekow, near Anklam, Pomerania, as the son of a vicar. After going to school in Anklam he studied theology from 1752 to 1756 in Halle. He then worked as a senior high school teacher in Erfurt (1758–1762). From this position, however, Adelung had to resign due to a confessional controversy. For the period 1762–1765 no certain details of his whereabouts are known; he was possibly a librarian at Gotha. The following years he spent at Leipzig, and, being unemployed, made a living as a translator and as an editor of various publications. In 1787, he was appointed head librarian of the electoral library of Dresden, whose organization he improved and developed. Adelung remained in Dresden until his death on the 10th of September 1806.

Figure 1 Portrait of Johann Christoph Adelung. Reproduced from Martin-Luther-Universitat, Halle-Wittenberg, with permission.

Adelung's work as a translator and as an editor of some 10 magazines and periodicals covered various fields, above all, history but also natural sciences, education, geography, and cultural history. This and, of course, his profession as a librarian gave him a very broad survey of the general state of the art of his time. In 1766, Adelung was commissioned by the publisher Breitkopf to continue the work on an extensive dictionary of the German language (German, Standard), which had only just been started by J. C. Gottsched. The five volumes with the title *Versuch eines vollständigen Wörterbuchs der hochdeutschen Mundart* were published between 1774 and 1786, and a second revised edition was published between 1793 and 1802 (*Grammatisch-kritisches Wörterbuch der hochdeutschen Mundart*), at the time the most extensive dictionary of the German language and its dialects. Henceforth the German language was Adelung's main field of interest as a scholar. Another commission by the Prussian Prime Minister, Baron von Zedlitz, was the starting point of his activities as a grammarian and resulted in the *Deutsche Grammatik* of 1781, followed by a simplified version intended for elementary schools that was also published in 1781. Very soon an extensive, explanatory version in two volumes (*Umständliches Lehrgebäude* and *Grundsätze der deutschen Orthographie,* 1782) of his school grammar appeared. Two previous publications on the history and origin of language (*Über die Geschichte der deutschen Sprache, 1780; Über den Ursprung der Sprache*, 1781) were included in the *Umständliches Lehrgebäude*. The latter also contains his theory of word formation, which he regarded as a historical process (etymology). In the periodical *Deutsches Magazin*, which appeared in two annual

volumes in 1782 and 1783, Adelung reviewed books on linguistics and discussed and defended the theories he had presented in the *Versuch* and the *Umständliches Lehrgebäude*. His numerous publications also cover the field of stylistics (*Über den deutschen Stil*, 1785, 1786), orthography, and pronunciation (*Vollständige Anweisung zur deutschen Orthographie,* 1788; *Kleines Wörterbuch für die Aussprache, Orthographie, Biegung und Ableitung,* 1781). Adelung also devoted himself to Gothic, Old, and Middle High German literature. In 1806, the first volume of *Mithridates,* a collection of the prayer 'Our father' in about 450 Asian languages, was published. After Adelung's death in 1806, the orientalist J. S. Vater took over this project and published three more volumes on European, African, and American languages (1809, 1812, 1817).

Characteristic of Adelung as a linguist is the breadth of his knowledge, his immense industry and diligence, and his sober and pragmatic view on language. He was a great collector, summing up and adapting the achievements of his predecessors to his own time. To a much lesser degree he was an innovator and a theorist. He often wavered between different standpoints, and it is not difficult to find inconsistencies and contradictions in his texts. His approach to language as a grammarian was empirical and psychological rather than logical, contrary to contemporary rationalist grammarians such as J. M. Roth or A. F. Bernhardi. His ideas about the history of language were to a great extent influenced by J. G. Herder. Thus, he regarded language as an invention of man, not a gift of God, and the development of language as parallel to that of human civilization and culture. Adelung's theory of the origin of language was onomatopoetic: words had arisen from the need to imitate natural sounds, and, in accordance to the primitive state of its inventors, the first words were obscure in meaning and monosyllabic in form. He regarded the dialect of Meissen in Southern Saxonia, which in his opinion was the culturally most flourishing province of Germany, as a prototype and model of Standard High German, a view that not unexpectedly led to controversies with other scholars.

Adelung can be regarded as a link between the linguistics of the Enlightenment and of Romanticism. In his methodical ambition, only to draw conclusions based on empirical data and by bringing the history of language into the scope of lexicography and grammar, he was a forerunner of comparative and historical linguistics. His historical work, especially the *Mithridates*, contained a huge amount of linguistic data, which, however, he could not fully work up theoretically. He was therefore widely ignored by historical and comparative linguists such as J. Grimm. It is significant that Grimm, in the preface of his *Deutsche Grammatik* of 1819, severely criticizing school grammar, only mentioned Adelung as an author of this kind of grammar. As to the synchronic part of his studies, i.e., the lexicographic mapping and the dialectological and grammatical description of the German of his time, Adelung's influence and importance, however, are unquestionable. The great number of editions of his dictionaries and grammars and the number of works based on Adelung's corpus that followed in Germany and other countries after his death bear good evidence of this.

Adjectives

R Pustet, University of Munich, Munich, Germany

General

Like the two other major parts of speech, noun and verb, adjectives can be defined at various levels of the organization of language, in particular, at the levels of morphosyntax, semantics, and syntactic usage. Statements regarding the universality or nonuniversality of the category of adjective in the languages of the world will always have to be made in the context of these individual levels of language description. From a semantic point of view, adjectives can be said to exist in any one language; however, morphosyntactically based definitions reveal that many languages do not have an independent class of adjectives. Morphosyntactic approaches to parts of speech operate by determining which individual lexical items can be combined with what types of grammatical items when used in syntactic context, and by investigating the position of individual lexical items relative to other constituents in higher-order syntactic configurations, as well as any additional structural characteristics of the lexical items in question. On the basis of differences between individual lexical items with respect to these criteria, lexical items can be assigned to distinct structural classes.

Adjectival Morphosyntax

Many languages do not have a structurally separate class of adjectives; in these languages, the morphosyntactic properties of the semantic equivalents of English adjectives are more or less identical to those of either the nominal or the verbal class. Thus, in Latin, the lexical representations of concepts that semantically correspond to English adjectives, by and large, exhibit the morphosyntactic characteristics of Latin nouns: for instance, they are inflected for gender, number, and case by means of affixes, and, like nouns, they require the presence of a copula in predicate position.

(1) vi-a long-a est
road-NOM.SG.FEM *long-NOM.SG.FEM* *is*
'the road is long'

In contrast, in Lakota, the semantic equivalents of English adjectives display the morphosyntactic properties of verbs. For instance, they combine with the person, number, and tense affixes used in verbal morphology:

(2) ṵ-wáš'aka-pi-kte
1PL.PAT-strong-PL-FUT
'we will be strong'

Another domain in which considerable cross-linguistic variation can be observed concerns the size of the adjective class in languages that have a structurally independent class of adjectives. For instance, English and Japanese are equipped with large adjective classes comprising thousands of members. In contrast, according to Dixon (1977: 20–22), there are also languages with extremely small adjective classes: in Igbo there are eight adjectives, in Pengo there are 20 adjectives, in Sango there are 30 adjectives, and in Bantu languages the size of the adjective class ranges between 10 and 50 members. Large adjective classes may at least in part be due to the existence of derivational processes in the languages in question, which allow the formation of new adjectival lexemes. In

Adjectives

R Pustet, University of Munich, Munich, Germany

General

Like the two other major parts of speech, noun and verb, adjectives can be defined at various levels of the organization of language, in particular, at the levels of morphosyntax, semantics, and syntactic usage. Statements regarding the universality or nonuniversality of the category of adjective in the languages of the world will always have to be made in the context of these individual levels of language description. From a semantic point of view, adjectives can be said to exist in any one language; however, morphosyntactically based definitions reveal that many languages do not have an independent class of adjectives. Morphosyntactic approaches to parts of speech operate by determining which individual lexical items can be combined with what types of grammatical items when used in syntactic context, and by investigating the position of individual lexical items relative to other constituents in higher-order syntactic configurations, as well as any additional structural characteristics of the lexical items in question. On the basis of differences between individual lexical items with respect to these criteria, lexical items can be assigned to distinct structural classes.

Adjectival Morphosyntax

Many languages do not have a structurally separate class of adjectives; in these languages, the morphosyntactic properties of the semantic equivalents of English adjectives are more or less identical to those of either the nominal or the verbal class. Thus, in Latin, the lexical representations of concepts that semantically correspond to English adjectives, by and large, exhibit the morphosyntactic characteristics of Latin nouns: for instance, they are inflected for gender, number, and case by means of affixes, and, like nouns, they require the presence of a copula in predicate position.

(1) vi-a long-a est
road-NOM.SG.FEM *long-NOM.SG.FEM* *is*
'the road is long'

In contrast, in Lakota, the semantic equivalents of English adjectives display the morphosyntactic properties of verbs. For instance, they combine with the person, number, and tense affixes used in verbal morphology:

(2) ṵ-wáš'aka-pi-kte
1PL.PAT-strong-PL-FUT
'we will be strong'

Another domain in which considerable cross-linguistic variation can be observed concerns the size of the adjective class in languages that have a structurally independent class of adjectives. For instance, English and Japanese are equipped with large adjective classes comprising thousands of members. In contrast, according to Dixon (1977: 20–22), there are also languages with extremely small adjective classes: in Igbo there are eight adjectives, in Pengo there are 20 adjectives, in Sango there are 30 adjectives, and in Bantu languages the size of the adjective class ranges between 10 and 50 members. Large adjective classes may at least in part be due to the existence of derivational processes in the languages in question, which allow the formation of new adjectival lexemes. In

English, for instance, adjectival lexemes can be created from various types of base lexemes by means of the highly productive derivational suffix *-y* (e.g., *fun* > *funny*, *to itch* > *itchy*). Other structural devices often used for the purpose of deriving adjectives include reduplication, internal modification, tone change, and compounding.

The inventories of the grammatical categories found in human languages differ considerably, both in complexity and with respect to the categories contained in them. For this reason, it is impossible to pin down an invariable, i.e., universal, set of grammatical categories that adjectives combine with in any language. However, certain morphosyntactic features tend to recur in the morphosyntactic profiles of adjectives at the cross-linguistic level. In what follows, a brief overview of the most important of these features is given.

Since gradability is an important semantic characteristic shared by many adjectival concepts (cf. 'Adjectival Semantics' below), grammatical devices for coding the semantic subcategories of gradation can be expected to be widely available in the languages of the world. This is indeed the case; the coding formats for concepts such as comparative, superlative, and elative include, among other things, affixes, adverbs, and more periphrastic construction types. Thus, English uses both affixation and adverbial modification to express the notions of comparative and superlative: *short-er*, *short-est* vs. *more intelligent*, *most intelligent*. In Bari, a construction involving a verb that can be translated by 'to exceed' is used to code the comparative.

(3) Körsuk a lokong to-tongun Jökö
K. is wise INF-exceed J.
'Körsuk is wiser than Jökö'

Further, in many languages, adjectives are combined with a copula in predicate position, as in Swahili:

(4) ki-su ni ki-kali
CL.SG-knife COP CL.SG-sharp
'the knife is sharp'

Adjectives often show agreement with the noun they modify, as in German:

(5) grün-e Bäum-e
green-NOM/ ACC.PL.MSC tree-NOM/ ACC.PL.MSC
'green trees'

There are languages in which a linker is inserted between a noun and an adjective that functions as an attribute of that noun, as in Indonesian:

(6) air yang dingin
water LK cold
'cold water'

Linker insertion may be either obligatory or optional in any attributive construction involving adjectival lexemes in a given language. However, there are also languages in which dispensability vs. strict requirement of a linker varies from lexeme to lexeme.

In some languages, such as Lakota, adjectival attributives form compounds with the noun they modify:

(7) thípi-ṡà ki
house-red the
'the red house'

In example (7), the adjectival attribute *-ṡà* 'red' receives secondary stress only (which is marked by `); consequently, the configuration of head noun and attribute is to be analyzed as a compound in this case.

Regarding the relative order of adjectives and other constituents within the noun phrase, Greenberg (1963: 87) notes that across languages, in configurations in which adjectival attributes, demonstratives, and numerals are present, when all of these noun phrase constituents either precede or follow the head noun, the adjectival attribute, rather than the modifying demonstratives and numerals, is the constituent that tends to be placed next to the head noun. The English example *these three red books* illustrates this.

Adjectival Semantics

According to the traditional semantic definitions of parts of speech, adjectives express property concepts. This distinguishes them from the two other major parts of speech, noun and verb, whose most prototypical representatives denote object concepts and event concepts, respectively. However, the semantic definition of 'adjective' as property concept, in many languages, merely captures the greater part of lexical items exhibiting the morphosyntactic features of adjectives (cf. 'Adjectival Morphosyntax' above). For instance, the lexeme *furious* must be classed as a member of the adjectival class of English on morphosyntactic grounds, but it designates a passing state rather than a property.

The notion of property concept can be further decomposed into semantic features. In this context, the features time-stability, stativity, and relationality (i.e., valence structure) turn out to be particularly salient and useful (Bhat, 1994; Croft, 1991; Givón, 1979; Pustet, 2000, 2003; Stassen, 1997; Wierzbicka, 1995). Prototypical adjectival concepts are characterized by:

1. intermediate time-stability (Givón, 1979: 321–322). Prototypical adjectival concepts are indeterminate as to the duration of the state of affairs they designate and thus cover either long or short time spans. For instance, the English adjective *gray* may be used to describe a house, but also the sky on a

particular day. When referring to a house, the state of affairs 'gray' is likely to have a long duration, which may extend over years or possibly decades. When referring to the sky, the state of affairs 'gray' is likely to change within days, hours, or even minutes.

2. stativity (Langacker, 1987; Wierzbicka, 1995). Prototypical adjectival concepts express static, rather than dynamic, states of affairs. For instance, a dynamic concept such as 'to go' involves changing internal states, such as movement of the feet, while the component states of a stative concept such as 'big' are identical to each other throughout the time span covered by the proposition 'big' in any given case.
3. a valence of 1, i.e., intransitivity (Croft, 1991: 62–63, 104–105; Langacker, 1987). Prototypical adjectival concepts require only a single valence slot to be filled when functioning as lexical heads of predicates. In many languages, the term 'subject position' is appropriate in referring to this valence slot. Thus, in order to use the English adjective *red* as the lexical head of a clausal predicate, the subject slot of the clause must be filled, as, for instance, in the example *the book is red*.

However, in any language, there may exist lexical items whose semantic feature profiles deviate from the above adjectival prototype even though they show adjectival morphosyntax. For instance, the English adjective *wooden* is maximally time-stable in semantic content; for an entity that consists of wood, according to the known physical laws of the universe, this property is impossible to change during the lifetime of that entity. *Dizzy*, on the other hand, is minimally time-stable in semantic content because a state of dizziness usually does not last very long.

Adjectival concepts that comply with the semantic prototype definition given above can be grouped into semantic classes. A well-known classification of the adjectival domain is given in Dixon (1977: 31). The classes listed by Dixon include dimension ('big', 'little', 'long', 'short', 'thick', 'thin', etc.), physical property ('hard', 'soft', 'hot', 'cold', 'sweet', 'sour', etc.), color ('black', 'white', 'red', etc.), human propensity ('happy', 'generous', 'clever', 'proud', etc.), age ('new', 'young', 'old', etc.), value ('good', 'bad', 'excellent', 'fine', etc.), speed ('fast', 'quick', 'slow', etc.). These semantic classes display cross-linguistically recurring properties with respect to the manifestation of the morphosyntactic patterns addressed in 'Adjectival Morphosyntax' above (Dixon, 1977: 56):

1. No matter how small the morphosyntactically, or structurally, defined adjective class in a given language may be, members of the semantic classes age, dimension, value, and color are likely to be contained in it.
2. In languages with small structural adjective classes, human propensity concepts tend to be realized in the structural class of nouns rather than in the adjectival class, while physical property concepts tend to be realized as structural verbs.

A semantic criterion that sets adjectival concepts apart from most nominal and verbal concepts is that they often imply the notion of scalar measurability. This characteristic is the conceptual basis for the grammatical feature of gradability: only concepts that exhibit scalar measurability in their semantic profile are gradable, and admit formation of antonym pairs such as 'big' vs. 'little'. There are, of course, adjectival concepts that are not scalar and thus not gradable. An example is 'empty'.

Syntactic Usage of Adjectives

Each of the major parts of speech – noun, verb, and adjective – can be assigned a preferred function in syntax. For adjectives, this function is that of attribute, as in *red book*. Needless to say, adjectives can also be used in their nonprototypical syntactic functions, i.e., in argument and predicate position. The latter functions are associated with nouns and verbs, respectively. These distributional patterns, which can be verified by means of discourse frequency counts, constitute a putative language universal (Croft, 1991: 36–98).

When used as attributes, adjectives frequently occur in the bare or structurally unmarked form (Croft, 1991: 36–98), although many languages are equipped with morphosyntactic elements that are used specifically with adjectives in predicate position. Examples include gender inflection in German (cf. [5]) and linker insertion in Indonesian (cf. [6]). When functioning as lexical heads of arguments or predicates, adjectives tend to combine with additional morphosyntactic material, which often merely contributes to marking the syntactic function in question. The contrast between the attributive and the predicative adjective constructions in *the red book* vs. *the book is red* illustrates this: a copula can be considered an example of such added morphosyntactic material that may be present when adjectives appear as lexical heads in a syntactic function in which they do not typically occur, in this case, in predicate position.

Further, syntactic function may impose restrictions on the use of adjectives in discourse. In many languages, certain adjectives are exempt from being used in specific syntactic functions. Takelma provides an

extreme example for such a restriction since in this language, all adjectives must be used attributively (Sapir, 1922). In English, there are adjectives whose occurrence is limited either to attributive or to predicative function (e.g., Bolinger, 1967; Quirk *et al.*, 1972: 234). Examples include *former* and *ready*; *former* is not acceptable as a predicate, while *ready* cannot occur as an attribute. Thus, *the former president* is grammatical, while **the president is former* is not; *the sandwich is ready* is grammatical, while **the ready sandwich* is not.

Adpositions

D Kurzon, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

Adposition is a cover term for both prepositions and postpositions. The grammatical treatment of adpositions has undergone considerable change over the last three decades or so. In traditional approaches, the adposition was viewed merely as a minor word class consisting of a small set of words; it was very often treated briefly within a page or so. The number of adpositions in languages that possess them tends to be in the range 20–30, although it is also possible to form compound adpositions, which may increase the number, for example, English *on account of*, French *à cause de*. Second, the traditional view sees the adposition as a word placed in front of the noun phrase (although adpositions may have other major phrase classes as objects or complements); hence, in such languages we identify a **pre**position (i.e., the word is placed before its complement). In other languages, an adposition is placed after the noun phrase, so we term it a **post**position. However, today, following advances in theoretical syntax, adpositions are considered in some treatments as one of the major word classes together with nouns, verbs, and adjectives/adverbs. In X-bar syntax, then, the adposition is the head of a phrase, a PP (which may be read as prepositional **or** postpositional phrase), followed by its complement (in the case of prepositions) or preceded by its complement (in the case of a postposition).

The two subclasses of adpositions may also reflect the distinction made in linguistic typology between head-first languages and head-last languages. In head-first languages, also known as SVO and VSO languages, which include languages in the western branches of Indo-European (e.g., the Celtic and

extreme example for such a restriction since in this language, all adjectives must be used attributively (Sapir, 1922). In English, there are adjectives whose occurrence is limited either to attributive or to predicative function (e.g., Bolinger, 1967; Quirk *et al.*, 1972: 234). Examples include *former* and *ready*; *former* is not acceptable as a predicate, while *ready* cannot occur as an attribute. Thus, *the former president* is grammatical, while **the president is former* is not; *the sandwich is ready* is grammatical, while **the ready sandwich* is not.

Adpositions

D Kurzon, University of Haifa, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

Adposition is a cover term for both prepositions and postpositions. The grammatical treatment of adpositions has undergone considerable change over the last three decades or so. In traditional approaches, the adposition was viewed merely as a minor word class consisting of a small set of words; it was very often treated briefly within a page or so. The number of adpositions in languages that possess them tends to be in the range 20–30, although it is also possible to form compound adpositions, which may increase the number, for example, English *on account of*, French *à cause de*. Second, the traditional view sees the adposition as a word placed in front of the noun phrase (although adpositions may have other major phrase classes as objects or complements); hence, in such languages we identify a **pre**position (i.e., the word is placed before its complement). In other languages, an adposition is placed after the noun phrase, so we term it a **post**position. However, today, following advances in theoretical syntax, adpositions are considered in some treatments as one of the major word classes together with nouns, verbs, and adjectives/adverbs. In X-bar syntax, then, the adposition is the head of a phrase, a PP (which may be read as prepositional **or** postpositional phrase), followed by its complement (in the case of prepositions) or preceded by its complement (in the case of a postposition).

The two subclasses of adpositions may also reflect the distinction made in linguistic typology between head-first languages and head-last languages. In head-first languages, also known as SVO and VSO languages, which include languages in the western branches of Indo-European (e.g., the Celtic and

Slavonic languages), major Semitic languages (e.g., Arabic and Hebrew), and African language families, we normally find prepositions, as illustrated in the following examples.

- English *on,* as in: on the table
- French *à,* as in: *à la maison* 'in the house/at home'
- Russian *v,* as in: *v dome* 'in the house'
- Welsh *ar,* as in: *ar y bwrdd* 'on the table'
- Arabic *'ala,* as in: *'ala iT-Taawilla* 'on the table'

Head-last languages, on the other hand, tend to be SOV languages. This set of languages includes languages belonging to the eastern branches of Indo-European (e.g., Persian), Indian languages (e.g., Hindi and Bengali), and languages in other families (e.g., Turkish, Japanese, and Korean). In these languages, we usually find postpositions. Hindi *par,* as in:

ghar	par		
home	on	=	'at home'

Turkish *için,* as in:

benim	için		
1.GEN	for	=	'for me'

and Turkish *(i)le/la,* as in:

trenle		
train.by	=	'by train'

The relationship between the position of the adposition and the type of language (SVO/VSO or SOV) may be seen only in terms of relative frequency. SVO languages, for example, may have one or two postpositions or may have a unique postpositional phrase. English, for example, has one postposition, the temporal adposition *ago* as in *three years ago*. German, an SOV language in many accounts, has prepositions only, with the exception of *nach*, a preposition that functions as a postposition in one expression only, *meiner Meinung nach* 'in my opinion'. Other languages that do not have the normally expected typological order include Finnish, an SVO language that has more postpositions than prepositions, and Persian, an SOV language that has prepositions only.

In Amharic, a Semitic SOV language spoken in Ethiopia, there are both prepositions and postpositions. There are a handful of very frequent prepositions, for example, *bä* 'with, by', *kä* 'from, out of', *wädä* 'toward, into', but most adpositions are postpositions, for example, *wəst* 'in', *lay* 'on'. Most postpositions derive from nouns and several derive from verbs, which is not the case with prepositions. There are also several mixed adpositions that use both a preposition and a postposition, for example, *lay* 'the top' becomes *ə . . . lay* 'on, at, of'; *kä . . . lay* 'down from, from above'. However, in colloquial Amharic, the tendency is to omit the preposition; thus speakers use the predicted word order Complement + Postposition of an SOV language.

In many languages with an overt case system, the adposition governs the case of the complement NP. For example, in Russian the preposition *iz* 'from' governs the genitive case, as in *iz komnaty* 'from the room'. In Slavonic languages, and also in German and Latin, some locative adpositions may govern more than one case depending on whether the meaning is locative or directional. So in German, the preposition *in* in *in das Haus* 'into the house', governs the accusative case, whereas in *in dem* (or *im*) *Haus* 'in the house' the same preposition governs the dative. In Standard (Classical) Arabic, all prepositions but one (*'ila'* 'except') govern the genitive case, for example, in *kilu min as-sukari* 'a kilo of sugar', the noun *as-sukar* is in the genitive (suffix-*i*). In modern spoken Arabic dialects, however, cases are no longer found. In English, five of the personal pronouns have retained an originally extended system of case endings: *she* becomes *her* as in *to her.*

In terms of morphology, it may be said that in most Indo-European languages, the adposition, whether it is a preposition or postposition, is indeclinable—it remains constant in form. So, we have in English *in*, *from*, *because of*, French *de* 'of, from', and *pour* 'for', Russian *iz* 'from', *dlya* 'for', Hindi *par* 'in', *tak* 'until, by'. However, in some Celtic languages we find a group of prepositions that are inflected when the complement of the preposition is a pronoun. In Welsh, for example, the preposition *er* 'for' is inflected according to person, number, and, in the third person, gender, for example, *erof* 'for me', *eroch* 'for you (plural)', *erddo* 'for him', *erddi* 'for her'. In Semitic languages, we find the same phenomenon, for example, in Arabic *min* 'from' gives *minhu* 'from him', and in Hebrew *le* 'to' gives *lanu* 'to us'.

The presence in some languages of inflected adpositions may be linked to the historical development of this word class in these languages. In some SOV languages, we find a form of inflected postposition, presumably because the postposition is often derived from a noun, which is subject to inflection. In Turkish there is a set of postpositions such as *için* 'for' and *doğru* 'toward', but there are also many adpositions that derive from nouns and have been termed 'fake' postpositions. For example, the noun *üst* 'top', is inflected as a normal noun:

üstünde		
top.GEN.LOC	=	'on top of, on'
üstünden		
top.GEN.from	=	'from the top'

To express 'on the table' and 'off the table,' this noun in the appropriate inflected form functions as a

postposition following the genitive form of the noun *masa* 'table':

masanin üstünde
table.GEN top.GEN.LOC = 'on the table'
masanin üstünden
table.GEN top.GEN.from = 'off the table'

A similar structure with a noun may be found in Vietnamese, where there are relator nouns; for example, *tren* means 'the top, higher point' and may function as a preposition, as in: *cái bút o tren bàn* 'the pen is on the table'.

As reflected in the examples from Turkish and Vietnamese, it may be said that in many languages we do not find adpositions as a separate word class but, rather, that adpositionlike structures are formed by combining words of different word classes and affixes. In the East African Bantu language Swahili, the *-a* of association (pronominal concord meaning 'of, for') is used to create phrases that have meanings found regularly with adpositions, as in *karibu na* 'near', in *karibu na ziwa* 'near a lake'. In Japanese, an SOV language, we find a similar structure with *no* as the relational particle and *ni* as a locational particle:

heya	no	naka	ni
room	RELPART	middle	LOC

'in the room'

We may examine the history of adpositions not only through their grammar but through their semantics, too. The semantic range of adpositions initially covered temporal and spatial locations (e.g., *in*, *on*, *after*, *until*), but over many centuries languages have extended the meanings of these adpositions to cover more abstract concepts; for example, the meaning of *after*, with its original temporal meaning 'following in time' and locative meaning 'behind,' has been extended to 'according to' or 'in imitation of', as in *The portrait was painted after Vermeer*. The meaning of *to* has been extended from its directional meaning to, among others, its use in the idiomatic phrasal verb *be up to something*.

Although we find adpositions in languages from all corners of the world, their occurrence may not be universal. In languages that have serial verbs, such as Akan and the Melanesian pidgins, we often find that the second verb may have the syntactic and semantic attributes of an adposition; for example, in Akan:

Kofi	fa-a	ntoma	ma-a	me
Kofi	take-PERF	cloth	give-PERF	me

'Kofi took a cloth for me'

Languages in which nouns have extensive inflection patterns seem to have less need of a separate adposition word class. The major (temporal and spatial) locatives are expressed by morphological patterns.

The center of attention as far as adpositions are concerned is without doubt their semantics. The multiple meaning of adpositions may be seen in terms of monosemy, homonymy, or polysemy. The first approach suggests that an adposition has a highly abstract meaning, but does not take into account how the context operates in attributing the correct meaning in any one case. Homonymy suggests that a different word derives from each meaning of an adposition. This approach ignores the historical development of adpositions; as mentioned previously, adpositions had far fewer meanings in the past. In terms of polysemy, the adposition is semantically underdetermined. The meaning in any given context may be understood through pragmatic means, for example, Grice's conversational implicatures, background knowledge, and relevance theory. This may be illustrated by the meaning of *over* in the sentence: *The athlete jumped over the hurdle*. In this sentence, *over* means 'starting from one side, making an arc, and landing on the other side' of the hurdle. But *over* in a sentence such as *The bird was hovering over the house* means 'above.' The basis on which the speaker decides which meaning applies to a particular sentence is not only linguistic knowledge but also cognitive processes, including background information. After the verb *jump,* some trajectory is expected, not a static location because we know from our experience in this world that athletes do not stay up in the air no matter how great their prowess in jumping. It should not be assumed, however, that without a context the preposition *over* is meaningless. After all, the difference between *The athlete jumped over the hurdle* and *The athlete jumped next to the hurdle* derives directly from the contrast between *over* and *next to*.

Highly polysemic adpositions have been termed colorless (or abstract or empty). Their meaning may be ascertained only from the context, whereas a colorful adposition has a short list of more precise meanings. In French, for example (the first language that was studied within this paradigm), the colorless prepositions are *à*, *en,* and *de* 'in/at', 'of', whereas colorful prepositions include *sans* 'without' and *durant* 'during'. In addition to colorless and colorful prepositions, French has a number of mixed prepositions, for example, *pour* 'for' and *par* 'by', which have their meaning extended according to context but in a more restrained way than the colorless prepositions.

If, then, the semantics of adpositions in natural languages leads to polysemy, either the meaning of

an adposition must be understood from the context, as illustrated, or the meaning is so vague that the adposition becomes meaningless. When this occurs, all that may be said about it is that it is the head of a prepositional (or postpositional) phrase. This occurs very conspicuously in pidgins and creoles. The preposition *long* in the Melanesian pidgin Bislama not only has a host of temporal and locative meanings determined by the context, for example, 'in, on, at, to', but plays, too, an important syntactic role in which it is semantically meaningless. *Long* marks the second object of a ditransitive verb, although this second object is often the indirect object, which in English and many other European languages may be marked by the preposition *to* or its equivalent. However, in

hem	i	tijim	mifala	long	matematik
he	PRED	teach	us	PREP	mathematics

'he teaches us mathematics'

it is clear that the prepositional phrase *long matematik* is not the equivalent of the English *to mathematics*, a prepositional phrase functioning as goal or recipient (indirect object), but is marked as the second complement in terms of word order.

A further example of an adposition becoming a syntactic marker is the English *to* when it functions as the marker of the verb infinitive (labeled in some syntactic theories as a complementizer). This function is similar in some respects to *à* and *de* in French, although in this language further morphological means are found (viz. suffixes such as *-er*, *-re*, *-ir*). This may be contrasted to languages such as Russian and Spanish, in which the infinitive is marked by suffix only, for example, *-at'/-it'* in Russian and *-ar/-ir* in Spanish.

Introduction

Adverbs easily constitute the most heterogeneous of all word classes; they often are described as a 'dustbin' category to which items will be assigned that do not fit into other word classes. Semantically and morphologically, adverbs are most closely related to adjectives, from which they are often derived.

The earliest attempts at defining adverbs reflect the etymology of the word (cf. Latin *ad-verbium*): adverbs are "used in construction with a verb" (Appolonios Dyscolos). Even today, manner adverbs are typically considered the core group of adverbs. One definition commonly encountered in linguistic textbooks is more general than the one proposed by scholars in classical antiquity: adverbs modify verbs, adjectives, or other adverbs. Apart from its patent circularity, the traditional textbook definition does not apply to countless items that are commonly classified as adverbs (e.g., words that usually relate to whole sentences, such as *fortunately*). Many linguists have tried to remedy the shortcomings of traditional accounts by assigning some putative 'adverbs' to other word classes (cf. 'Semantics versus syntax').

Semantic Categories

Of the many semantic classifications of adverbs that have been suggested, the following semantic subclasses seem to have the widest currency in the

an adposition must be understood from the context, as illustrated, or the meaning is so vague that the adposition becomes meaningless. When this occurs, all that may be said about it is that it is the head of a prepositional (or postpositional) phrase. This occurs very conspicuously in pidgins and creoles. The preposition *long* in the Melanesian pidgin Bislama not only has a host of temporal and locative meanings determined by the context, for example, 'in, on, at, to', but plays, too, an important syntactic role in which it is semantically meaningless. *Long* marks the second object of a ditransitive verb, although this second object is often the indirect object, which in English and many other European languages may be marked by the preposition *to* or its equivalent. Adverbs

V Haser and B Kortmann, University of Freiburg, Freiburg, Germany

Introduction

Adverbs easily constitute the most heterogeneous of all word classes; they often are described as a 'dustbin' category to which items will be assigned that do not fit into other word classes. Semantically and morphologically, adverbs are most closely related to adjectives, from which they are often derived.

The earliest attempts at defining adverbs reflect the etymology of the word (cf. Latin *ad-verbium*): adverbs are "used in construction with a verb" (Appolonios Dyscolos). Even today, manner adverbs are typically considered the core group of adverbs. One definition commonly encountered in linguistic textbooks is more general than the one proposed by scholars in classical antiquity: adverbs modify verbs, adjectives, or other adverbs. Apart from its patent circularity, the traditional textbook definition does not apply to countless items that are commonly classified as adverbs (e.g., words that usually relate to whole sentences, such as *fortunately*). Many linguists have tried to remedy the shortcomings of traditional accounts by assigning some putative 'adverbs' to other word classes (cf. 'Semantics versus syntax').

Semantic Categories

Of the many semantic classifications of adverbs that have been suggested, the following semantic subclasses seem to have the widest currency in the

pertinent literature (examples and classification from Ramat and Ricca, 1994: 307f):

1. predicate adverbs (*quickly*, *already*, *repeatedly*, *again*)
2. degree adverbs (*very*, *extremely*)
3. sentence adverbs (*unfortunately*, *strangely*, *probably*, *allegedly*, *frankly*)
4. setting adverbs of space and time (*today*, *now*, *here*, *recently*)
5. focalizers (*only*, *also*, *even*)
6. text adverbs (*firstly*, *consequently*, *however*, *hence*).

Following Ramat and Ricca, predicate adverbs modify verbs or verb phrases, whereas degree adverbs modify adjectives and other adverbs. The class of sentence adverbs includes many different types of items. Their defining characteristic is that their scope extends over more than one constituent. Setting adverbs and focalizers lack many characteristic features of adverbs (cf. below). Text adverbs "give textual coherence to a sequence of sentences," and thus are similar in function to conjunctions (Ramat and Ricca, 1994: 308). It is not always easy to differentiate between text adverbs and conjunctions. One crucial difference is that the former function as adverbials. Moreover, conjunctions create a higher-order syntactic unit by joining two smaller syntactic units. By contrast, text adverbs merely connect units (viz. complete sentences) that remain syntactically independent.

Syntactic Functions

Typically, adverbs and adverb phrases have either of two syntactic functions (cf. Quirk *et al.*, 1985: 439f): They can occur as adverbials (e.g., *never* in *Tom never loses his temper*) or as premodifiers of adjectives (***extremely*** *sad*), adverbs (***extremely*** *quickly*), and (according to some definitions) nouns or noun phrases (***even*** *George*). According to some linguists, adverbs and adverb phrases can also function as arguments (e.g. as subject in *Tomorrow will be fine*; Quirk *et al.*, 1985: 440). It is not clear, however, whether *tomorrow* in this example should be counted as an adverb in the first place (cf. Semantics vs. syntax).

Coherence of the Word Class: Defining Criteria

The heterogeneity of the class of items commonly labeled *adverbs* prompts the question how to justify the postulation of a single category covering all these lexemes. The basis for such a justification should be the iconicity hypothesis, according to which "the concepts that fall into the same grammatical category are cognitively similar in some respects" (Croft, 2003: 204). This similarity may be reflected in the presence of necessary or sufficient semantic or syntactic features shared by all items classified as adverbs. Alternatively, it may be reflected in the presence of prototypical adverbs, to which the more marginal members of the class bear a sufficient similarity – although what counts as 'sufficient' similarity is a matter of debate. The following morphosyntactic features have been suggested as unifying characteristics of all or at least the prototypical adverbs in English: (i) adverbs are invariable; (ii) adverbs are optional; (iii) adverbs can be modified by items such as *very* or *quite*; (iv) adverbs are used as modifiers of categories other than nouns (e.g., Ramat and Ricca, 1994; Tallerman, 1998; Huddleston and Pullum, 2002). The first two features are at best necessary criteria (because prepositions and conjunctions, for example, also are invariable; and adjectives also often are optional). In a sense, the second criterion does not invariably apply even to typical adverbs. Certain verbs do require the presence of adverbs or other items functioning as adverbials (e.g., *The job paid us handsomely*; **The job paid us*; Jackendoff, 1972: 64), but these are exceptional cases. The third criterion only applies to prototypical adverbs. The fourth criterion is a good candidate for a defining feature, but it entails that certain items discussed below are excluded from the class of adverbs.

Semantics versus Syntax

In light of these four morphosyntactic criteria, close scrutiny of the six semantic categories of adverbs mentioned above reveals that some of these categories are problematic. For example, focalizers (group 5) should not be classified as adverbs, primarily because they serve to modify nouns (e.g., *only/even George*); also, they do not combine with typical adverbial modifiers like *very* or *quite*. Similar problems arise with setting adverbs (group 4). There is some evidence, though, that some of the examples which Ramat and Ricca group under this heading are more akin to (pro)nouns than to adverbs proper. For instance, items such as *today* or *tomorrow* can be found in argument positions usually occupied by noun phrases (e.g., they can function as subjects or complements of prepositions, as in *She'll be ready by tomorrow*). Furthermore, *today* and similar lexemes behave like nouns in that they can take the possessive *'s* (cf. Tallerman, 1998: 48f). In contrast to typical adverbs, these lexemes do not permit modifiers such as *very* or *quite,* and may even be obligatory (e.g., *here* in *put it here*). Most important, setting 'adverbs' do not

always act as modifiers: *here* in *put it here* does not really **modify** the verb (for a parallel argument relating to *outside*, cf. Huddleston and Pullum, 2002: 564). There are thus quite a few features that warrant excluding items such as *today* or *tomorrow* from the class of adverbs.

Other setting adverbs do not qualify as nouns but, rather, as prepositions. Thus, lexemes such as *there* can be plausibly reanalyzed as prepositions, primarily because they take modifiers that usually only modify prepositions, like *right* in *right there* (cf. Aarts, 2001: 184f for a number of arguments). Some setting adverbs, however, do seem to be clear adverbs (e.g., *recently* does not exhibit most of the above-mentioned 'deviant' features). The example of setting adverbs shows that the semantic subcategories traditionally posited for adverbs have to be subjected to careful analysis. Moreover, it is not always easy to draw the boundary between adverbs and nouns, or between adverbs, prepositions and conjunctions. Some scholars also argue that there is a certain overlap between adverbs and adjectives (cf. Quirk *et al.*, 1985: 403–409).

In light of the foregoing discussion, a definition of adverbs along the lines of Huddleston and Pullum (2002: 563) seems particularly promising. The authors capture "the most important defining property of adverbs" as follows: "Adverbs characteristically modify verbs and other categories except nouns." This definition is an improvement on the traditional textbook definition – adverbs modify verbs, adjectives, or other adverbs – because it also covers lexemes that modify larger syntactic units such as clauses (e.g., *perhaps*). Furthermore, it specifically excludes nouns as the only category that cannot be modified by adverbs and thus allows us to draw a relatively neat distinction between adjectives and adverbs. Note that this definition does allow for adverbs that modify noun **phrases**, as opposed to mere nouns. More specifically, "adverbs do not occur as attributive modifiers within a nominal" (**his almost success*), although they may modify a noun phrase (*almost the whole season*; Huddleston and Pullum, 2002: 563). Attributive modifiers within nominals are always adjectives; thus, *only* in *only his child* is an adverb, *only* in *his only child* is an adjective. Huddleston and Pullum's definition holds out the promise for a more succinct conception of adverbs for the following reason: those items that by this definition should be excluded from the category of adverbs (e.g., *tomorrow*) also usually fail to exhibit many other typical features of adverbs. For the same reason, a definition that requires that adverbs function as modifiers may be preferable to conceptions that additionally allow for a predicative use or other uses of adverbs (e.g., Huddleston and Pullum themselves or Hengeveld, 1992).

Semantics Complements Syntax: A Prototype Approach

A syntactic definition of adverbs should be complemented by a semantic characterization. Such a characterization necessarily focuses on prototypical adverbs, as it seems impossible to capture the common denominator of all adverbs in semantic terms. A compelling approach to defining parts of speech in semantic terms has been put forward by Croft (2001), who argues that a universally applicable definition of parts of speech has to be framed in terms of prototypes (for another intriguing explanation, cf. Sasse, 1993). Croft proposes a scheme based on pairings of semantic class (object, action, property) and propositional act functions (reference, modification, predication). The author suggests the following definitions: noun = 'reference to an object'; adjective = 'modification by a property'; verb = 'predication of an action.' Croft's original scheme only covers modification of a referent, but, as noted by the author himself, can be expanded to cover adverbial modification, which he captures as "modification of a predicate" (Croft, 2001: 94). Prototypical adverbs, much like prototypical adjectives, could then be defined as items that provide 'modification by a property,' the difference being that prototypical adjectives modify referents and prototypical adverbs modify predicates. This definition reflects the close link between adjectives and adverbs: Many adverbs are formed from adjectives (e.g., by means of *–ly* in English); and numerous languages do not even make a formal distinction between adjectives and adverbs. For example, non-standard varieties of English generally dispense with the typical adverb ending *–ly*. According to Hengeveld's Part-of-speech hierarchy (Verb > Noun > Adjective > Adverb), "a category of predicates is more likely to occur as a separate part of speech the more to the left it is in this hierarchy" (Hengeveld, 1992: 70).

Items that qualify as prototypical adverbs by Croft's definition (viz. manner adverbs) exhibit all the previously mentioned syntactic criteria of adverbs. Manner adverbs are invariable and almost always optional; they act as modifiers (but never modify nouns), and they can be modified by words like *very* or *quite*. In contrast to problematic items like *today* or *aboard*, they can never follow a copular verb. Most members of the remaining subcategories lack at least one of these features (e.g., they cannot be modified by degree adverbs). Our approach is cognitivist in spirit, as word classes are seen as having a

"prototype structure, with central members sharing a range of both syntactic and semantic attributes. Failure of an item to exhibit some of these attributes does not of itself preclude membership" (Taylor, 1995: 196). Such an approach is not at odds with the idea that all adverbs have at least one feature in common.

Introduction

In the 2nd millennium B.C.E., literacy spread from Mesopotamia and Egypt to adjacent parts of the eastern Mediterranean area. There can be little doubt that the Semitic consonantal alphabet (*abjad*) was directly inspired by Egyptian logoconsonantal writing. In the case of the essentially logosyllabic Sumero–Akkadian cuneiform writing system, it is, however, not entirely clear whether the creation of several logosyllabic and syllabic writing systems in the 2nd millennium B.C.E. was directly inspired by the principles behind the cuneiform script or only very loosely so.

Three such logosyllabic and syllabic writing traditions are known: the Byblos (pseudohieroglyphic) script of Phoenicia (*see* **Scripts, Undeciphered**), the Cretan–Mycenean–Cypriot scripts (Cretan hieroglyphic, Linear A, Linear B, the Phaistos Disk script, Cypro–Minoan, and the Cypriot syllabary), and the Anatolian hieroglyphs (a.k.a. Hittite hieroglyphs or Luwian hieroglyphs). Of these, only Linear B, the Cypriot syllabary (both mainly used to write Greek), and the Anatolian hieroglyphs (mainly used to write the Luwian language) have been wholly or largely deciphered.

General Characteristics of Open Syllabaries

The main point of agreement between the deciphered (logo)syllabic scripts previously enumerated is that they are basically **open** syllabaries; that is the syllabic signs are overwhelmingly of the type (C)V. We may provisionally assume that the same goes for the as yet undeciphered syllabaries. This contrasts, on the one hand, with Sumero–Akkadian cuneiform, whose syllabic signs are a mix of (C)VC and (C)V, and, on the other, with Egyptian hieroglyphics and the Semitic *abjad*, which are (logo)consonantal systems (i.e., the signs denote one or more consonants, but the quality and quantity of the vowels, or lack thereof, are not expressed in the writing).

"prototype structure, with central members sharing a range of both syntactic and semantic attributes. Failure of an item to exhibit some of these attributes does not of itself preclude membership" (Taylor, 1995: 196). Such an approach is not at odds with the idea that all adverbs have at least one feature in common.

Introduction

In the 2nd millennium B.C.E., literacy spread from Mesopotamia and Egypt to adjacent parts of the eastern Mediterranean area. There can be little doubt that the Semitic consonantal alphabet (*abjad*) was directly inspired by Egyptian logoconsonantal writing. In the case of the essentially logosyllabic Sumero–Akkadian cuneiform writing system, it is, however, not entirely clear whether the creation of several logosyllabic and syllabic writing systems in the 2nd millennium B.C.E. was directly inspired by the principles behind the cuneiform script or only very loosely so.

Three such logosyllabic and syllabic writing traditions are known: the Byblos (pseudohieroglyphic) script of Phoenicia (*see* **Scripts, Undeciphered**), the Cretan–Mycenean–Cypriot scripts (Cretan hieroglyphic, Linear A, Linear B, the Phaistos Disk script, Cypro–Minoan, and the Cypriot syllabary), and the Anatolian hieroglyphs (a.k.a. Hittite hieroglyphs or Luwian hieroglyphs). Of these, only Linear B, the Cypriot syllabary (both mainly used to write Greek), and the Anatolian hieroglyphs (mainly used to write the Luwian language) have been wholly or largely deciphered.

General Characteristics of Open Syllabaries

The main point of agreement between the deciphered (logo)syllabic scripts previously enumerated is that they are basically **open** syllabaries; that is the syllabic signs are overwhelmingly of the type (C)V. We may provisionally assume that the same goes for the as yet undeciphered syllabaries. This contrasts, on the one hand, with Sumero–Akkadian cuneiform, whose syllabic signs are a mix of (C)VC and (C)V, and, on the other, with Egyptian hieroglyphics and the Semitic *abjad*, which are (logo)consonantal systems (i.e., the signs denote one or more consonants, but the quality and quantity of the vowels, or lack thereof, are not expressed in the writing).

The genesis of the Sumero–Akkadian and Egyptian-Semitic writing systems is critically connected to certain characteristics of the underlying languages (Sumerian and Egyptian, respectively). The invention of the concept of writing itself (i.e., the use of pictures and symbols to denote language sounds) can most naturally occur if the underlying language is predominantly monosyllabic (as is the case in Sumerian). The resulting writing system will be logosyllabic, with syllabic signs for all the possible word/syllable structures of the original language (V, CV, VC, and CVC, in the case of Sumerian). The evolution of a logoconsonantal system such as the Egyptian one, and the subsequent development of a monoconsonantal script such as the Semitic *abjad*, also depends crucially on certain phonotactic and structural characteristics of the underlying languages, such as the lack of vowel-initial words and the alternation within a semantic group or a grammatical paradigm of forms with different vowels (or no vowel at all) but in a fixed consonantal framework, as can be found in Afroasiatic languages such as Egyptian and Semitic.

Open syllabaries, however, based on the use of pictograms to acrophonically denote the initial vowel or consonant + vowel of the object depicted, seem to represent a very intuitive and practical concept generally, provided the concept of writing itself has already been discovered. The creation of such writing systems does not appear to depend on the specific characteristics of the underlying language; in particular, it does not depend on the language having exclusively open syllables. It may, therefore, have been invented at several times and in several places independently, which may well be the case for the three traditions (Byblos, Aegean, and Anatolian) previously described.

If an open syllabary is used for a language that does not exclusively have syllables of the type V or CV, as is the case in Greek and Luwian, certain conventions need to be used in order to render those speech patterns of the language that cannot be written straightforwardly, such as consonant clusters and final consonants. Some of these conventions are quite universal. Geminate consonants are written as single consonants and, if another vowel follows after a consonant cluster, the sequence is written using an echo of that following vowel (e.g., Linear B **ku-ru-so** for /k^{h}rusos/ 'gold'). Final consonants can be written using an empty or 'dead' vowel, the nature of which depends on convention: Hieroglyphic Luwian uses **Ca** signs (e.g., **wa-wa-sa** = /wawas/ 'cow)' whereas the Cypriot syllabary uses **Ce** signs (e.g., **a-to-ro-po-se** = /ant^{h}ro:pos/ 'man'). If the syllable-final consonant is not a stop but a sonorant or fricative, it can be omitted altogether. In Linear B, this is the norm for all syllables ending in *-j*, *-n*, *-l*, *-r*, and *-s* (e.g., **po-me** = /poime:n/ 'shepherd,' **a-to-ro-qo** = /ant^{h}ro:k^{w}os/ 'man,' **ka-ko**/k^{h}alkos/, **ko-wo** /korwos/ 'boy,' **pe-ma**/spermal/ 'seed') An exception are diphthongs in *-w*, which are written with the sign **u** (e.g., **e-u-ke-to** /euk^{h}etoi/ '(s)he swears'), and sometimes syllables ending in *-m* (e.g., **a-mi-ni-so**/amnisos/ 'Amnisos'). In the Cypriot syllabary (Cypr.) and in Hieroglyphic Luwian (HLuw.), the practice of completely omitting the syllable-final consonant is only applied to nonfinal syllables ending in *-n* (e.g., Cypr. **a-to-ro-po-se** /ant^{h}ro:pos/ 'man,' HLuw. DEUS-TONITRUS-**hu-za** /tarxunts/ '(the god) Tarḫunt'), although in some Luwian inscriptions the practice is extended to all final consonants.

We may assume that all symbols started out as pictograms/logograms. But in a predominantly polysyllabic language, the signs could also be used to denote the first vowel or consonant + vowel of the word (e.g., Luwian 𔓐 is logographically *targasna* 'donkey' or syllabically *ta*). As the writing systems developed, some symbols became specialized as logograms, others became specialized as syllabograms, and yet others could be used in both functions. The purely syllabic signs naturally had a tendency to become less pictorial and more linear or 'cursive' over time, both because of the loss of association with the object originally depicted and because of their heavy use as syllables. Another tendency was to reduce the number of symbols that could be used to write a single syllable, ultimately to one – the Hieroglyphic Luwian syllabograms cannot be put into a neat syllabic grid as the Linear B syllabograms can (although in Linear B there are still a handful of alternative signs for certain syllables), and the Cypriot syllabary follows the principle of 'one syllable, one sign' almost exclusively. Another common characteristic of the ancient Aegean and Anatolian open syllabaries is the tendency for the logographic element of the scripts to become less prominent over time. This is most readily seen in the history of the Anatolian hieroglyphs, in which the oldest inscriptions often use only a logogram or a logogram with a phonetic complement used to specify the case or verbal form. Later, the normal spelling adds more syllables of the root or becomes completely syllabic, as shown in Table 1.

It is difficult to say how large the logographic component was in Cretan hieroglyphic (the probable ancestor of Linear A, Linear B, and Cypro–Minoan), but it is likely that many of the signs had an exclusively or partially logographic value. Linear A and B, on the other hand, use logograms only in conjunction with numerals, to denote what is being counted. For instance (tablet PY Eb297):

Table 1 Anatolian Hieroglyphs – Logogram with phonetic complements

Hieroglyphs	*Transliteration*	*Word*
	BOS	/*wawas*/'cow'
	BOS-sa	
	BOS-wa-sa	
	wa-wa-sa	

wa-na-ka-te-ro te-me-no
wanakteron temenos
'the estate of the king'

to-so-jo pe-ma WHEAT **30**
tossojo sperma: PUROS *30*
'so much seed: 30 units of wheat'

ra-wa-ke-si-jo te-me-no WHEAT **10**
la:wa:gesion temenos PUROS *10*
'the estate of the lawagetas: 10 units of wheat'

A millennium later, the Cypriot syllabary uses no logograms at all.

Linear B

The Linear B script was used on Crete and the Greek mainland (Mycenae, Pylos, etc.) for the purpose of keeping palace records from ca. 1550 to 1200 B.C.E. Most of the surviving texts were inscribed on clay tablets that got accidentally burnt. The first tablets were found in 1900 by Arthur Evans at the site of the Minoan palace of Knossos, on Crete. Not many of them, however, were published right away, and it was not until the discovery by Carl Blegen in 1939 of a large number of Linear B tablets at the site of Pylos, on the Greek mainland, and after their subsequent publication by Emmett L. Bennett in 1951 that a decipherment of the script became possible.

Decipherment

In order to decipher an unknown script in an unknown language when no bilinguals are available, it is necessary to have a sufficient amount of accurately described data so that statistical analyses can be performed and patterns can be discovered. Some of the ground-breaking work in the case of Linear B had already been done by Alice E. Kober in the years between 1943 and 1950. She had discovered that Linear B used two different forms for the totaling formula: one for women and female animals, another for men and male animals. She also discovered the so-called 'Kober triplets' – words that occurred in one short form, as well as in two derived forms, with the final syllabogram of the basic form replaced systematically by a couple of others, forming several patterns:

A	-𐀲	-𐀲𐀀	-𐀲𐀍
B	-𐀍	-𐀍𐀀	-𐀍𐀍
C	-𐀏	-𐀏𐀀	-𐀏𐀍
D	-𐀊	-𐀊𐀀	-𐀊𐀍
E	-𐀁	-𐀁𐀀	-𐀁𐀍

The system of numerals, measures and weights was elucidated by E. L. Bennett in 1950. The complete decipherment was achieved by the architect Michael Ventris in 1952. In reaching his solution, Ventris had combined several statistical and combinatorial clues. For instance, in an open syllabary, the signs for pure vowels occur mainly at the beginning of a word (fortunately, the Linear B scribes were careful to mark word division consistently). At the end of the word, some suffixes (consonant-initial ones) are found as syllabic signs that may or may not be found appended to the basic stem (a very common one in Linear B is -𐀆, which we now know to be $-k^{w}e$ 'and'). Other suffixes manifest themselves as variations of the final syllabogram(s), as for instance in the case of Kober's triplets, and such variant syllabograms can thus be interpreted as representing the same consonant followed by different vowels. Other clues can be found in spelling errors and spelling variants, indicating that the signs in question share a common consonant or a common vowel. Putting all these clues together, Ventris started to elaborate a grid, listing all the probable vowel and consonant combinations in tabular form. By February 1952, Ventris's grid (see **Figure 1**) was already largely correct. All that was required now was to guess at the appropriate sound values (a couple of them, such as C12 = /l/ ~ /r/, C8 = /n/, C3 = /p/, C7 = /s/ and C5/6 = /t/ ~ /d/ readily suggested themselves by comparison with the Cypriot shapes) and see whether the resulting readings made sense in any known language. Ventris himself had always believed (with Evans) that the underlying language could not possibly be Greek and would prove to be a pre-Greek Aegean language, perhaps distantly related to Etruscan. However, in May/June 1952, Ventris started to investigate some of the words forming part of Kober's triplets. By guessing that the words of this category that occurred both at Pylos and Knossos must be the names of corporations, and those that occurred at Knossos alone or at Pylos alone would be place names, he succeeded in isolating the Cretan place names **ko-no-so** (Knossos) and the nearby

harbor town of **a-mi-ni-so** (Amnisos), the latter with Kober variants **a-mi-ni-si-jo** and **a-mi-ni-si-ja**. Ventris noted that these corresponded exactly with the Greek adjectival forms masc. *amnisios*, fem. *amnisia:*, provided the spelling rules for final *-s* differed from those of Cypriot. This was further confirmed by the genitives: masc. **-jo-jo**, as expected, but fem. **-ja**, identical to the nominative, for what would have been the Greek fem. genitive *-ja:s*. A similar 'abbreviation in the spelling' was also found by Ventris in the words for 'boy' and 'girl,' which were expected to have been **korwos* and **korwa:* in archaic Greek. Having identified the sign **ko** in **ko-no-so**, the words for 'boy' and 'girl' (already identified thanks to the logograms accompanying them) now read **ko-ʔo** and **ko-ʔa**. Filling in the syllables **wo** and **wa**, that yielded **ko-wo** = *ko(r)wo(s)* 'boy' and **ko-wa** = *ko(r)wa:* 'girl.' Now, if C2 in Ventris's grid was /w/, that immediately suggested a solution for the group of words that declined as -Ce-𐀳, -Ce-𐀲, and -Ce-𐀱, which Ventris had already looked into before. They must be the well-known category of Greek words in *-eus* (e.g., Grk. *basileus*, gen. *basile:[w]os*, 'king,' etc.), and the Linear B paradigm could be read as *-eu*, *-ewo(s)*, *-ewe*. Similarly, the totaling formula could now be read as masc. **to-so**, fem. **to-sa**, corresponding with Greek *tossos*, *tossa:*. The Greek solution was now inescapable. Ventris, in collaboration with John Chadwick, published his results in the 1953 *Journal of Hellenic Studies* under the title 'Evidence for Greek dialect in the Mycenaean archives.'

Before the correctness of Ventris's solution had had the time to become a matter of hot academic dispute, evidence was unearthed at Pylos by Blegen that

Vowels	I (=i?)	II (=o?)	III (=e?)	IV	V (=a?)	unknown

	consonant or vowel wrong
	consonant and vowel wrong

Figure 1 Ventris's grid (February 1952).

convinced all but those few who had made up their minds not to be convinced. Tablet PY Ta 641, found just after Ventris's decipherment, reads as follows:

- ti-ri-po-de ai-ke-u ke-re-si-jo we-ke TRIPOD 2
  ti-ri-po e-me po-de o-wo-we TRIPOD 1
  ti-ri-po ke-re-si-jo we-ke a-pu ke-ka-u-me-no ke-re-ha [
- qe-to PITHOS 3 di-pa me-zo-e qe-to-ro-we DEPAS-4 1
  di-pa-e me-zo-e ti-ri-o-we-e DEPAS-3 2
  di-pa me-wi-jo qe-to-ro-we DEPAS-4 1
- di-pa me-wi-jo ti-ri-jo-we DEPAS-3 1
  di-pa me-wi-jo a-no-we DEPAS-0 1

This fully confirmed Ventris's solution; we find the Greek words *tripode* (dual) and *tripo:s* (singular) next to what are described ideographically as two and one tripod, and pictures of vessels with, respectively, four, three, and no ears are accompanied by the corresponding archaic Greek words *k^{w}etro:we:s*, *tri(j)o:we:s*, and *ano:we:s* (cf. Classical *amp^{h}o:e:s* 'two-eared').

The Syllabary

The sound values and shapes of the Linear B syllabary are given in Figure 2. Some of the common ideograms can be found in Figure 3.

There are five vowels; vowel length is not marked. The consonants show a number of peculiarities. In the stops, **p**-, **k**-, and **q**- can denote any labial, velar, or

labiovelar stop, voiced, voiceless, or aspirated. In other words, the sign **pa** can stand for /ba/, /pa/, /p^{h}a/ (and, because of the spelling rules, also /bal/, /pal/, /p^{h}al/, /bar/, /par/, /p^{h}ar/, /bam/, /pam/, /p^{h}am/, /ban/, /pan/, /p^{h}an/, /bas/, /pas/, /p^{h}as/, /bai/, /pai/, and /p^{h}ai/, as well as /ba:/, /pa:/, /pha:/, /ba:l/, /pa:l/, /p^{h}a:l/, etc.). The exception is the **t** series, which can denote syllables beginning with /t/ or /t^h/; syllables beginning with /d/ have their own symbols. Why this is so is a mystery. We can attribute it to a phonetic/phonotactic peculiarity of (one of) the pre-Greek language(s) of Crete. This inconsistency has been corrected in the Cypriot syllabary, which does not distinguish a separate **d** series anymore. Also attributable to the non-Greek origin of the Linear B script is the fact that /l/ and /r/ are not distinguished, another thing that was set right in Cypriot.

The optional syllabic signs include a number of signs denoting dental + /w/, as well as three variants of the main syllabic signs, apparently without any difference in pronunciation: **ro$_2$**, **ta$_2$**, and **pa$_3$**. (The last is not **pa$_2$** because of the historical circumstance that the sign **qa** was at first erroneously identified by Ventris and Chadwick as **pa$_2$**.) The existence of such variant signs is a remnant of a situation comparable to what we find in the Anatolian syllabary, in which many syllables have two or more alternative spellings. In addition to signs denoting diphthongs (**ai, au, rai, rja**), it is surprising to find a notation for **ha** and **phu**, with the aspiration marked explicitly, and for **pte**, the only CCV sign in the syllabary in which both consonants are stops and where the cluster /pt/ is quite characteristic for the Greek language.

A few signs function both as syllabograms and as ideograms, as shown in Table 2. As can be seen, the acrophonic principle fails for Greek, which again confirms that the syllabary was designed for some pre-Greek language of Crete. However, the sound–meaning pairs in Table 2 do not immediately suggest any other candidate language. Nor do the phonetic clues provided by the syllabic grid, although there we must proceed with caution. To find the 'Minoan language,' or one of its close relatives, it does not follow that we should look for a language that does not distinguish /l/ and /r/, /b/ and /p/, and /g/ and /k/ but that **does** distinguish /d/ and /t/. In the first place, it is only required by the acrophonic principle that those sounds not be distinguished in **word-initial** position. Greek itself at some stage did not distinguish /l-/ from /r-/ (more accurately, it had eliminated all cases of initial *r*-), although by Mycenean times, the initial sequence **sr*- had become *rh*-, which would presumably have been written **r**-, had a separate sign for it been available. Voiced and voiceless stops are not generally distinguished in the Indo–European Anatolian languages (which only had voiceless stops initially) or in ancient Iberian (which had only voiced stops initially). Both language groups incidentally also lack initial *r*-. As to initial *d*-, things also need not be so simple. It is possible that the 'Minoan language' distinguished two kinds of initial dental stops (*d*- and *t*- in Linear B) but also two kinds of initial velar stops (*q*- and *k*- in Linear B), and that the system was in fact not **p*-; **t*-, **d*-; **k*-, **k*^{w}- but conceivably something like **p*-; **t*-, **t′*-; **k*-, **k′*-.

The Cypriot Syllabary

The Cypriot syllabary was used on the island of Cyprus until Hellenistic times, mainly to write the local Greek dialect, although a few poorly understood inscriptions also exist in a non-Greek local language called Eteo–Cypriot.

The roots of the Cypriot syllabary go back to the Bronze Age. At Enkomi, and elsewhere on Cyprus, inscriptions have been found from the 15th to 12th centuries B.C.E. in a script (or scripts) known as Cypro-Minoan. There is not enough material to allow a decipherment, but there can be little doubt that the script is an offshoot of the Cretan linear scripts, in particular of Linear A. An inscription on a bronze dagger from the 11th century can be read using the Cypriot syllabary sign values as **o-pe-le-ta-u** (/op^{h}el-ta:o/ 'of Opheltes'), but otherwise the earliest inscriptions in the Cypriot syllabary date from the 8th century B.C.E., and they do not become abundant until the 6th century. The best-known Cypriot inscription is a very well preserved 5th-century bronze tablet from Idalion, containing a long text in the ancient Cypriot dialect of Greek. There are also a number of Cypriot–Alphabetic Greek and Cypriot–Phoenician bilinguals, which played an important role in the decipherment of the script.

Decipherment

The Cypriot syllabary was deciphered in 1872 by the Assyriologist George Smith after the discovery in 1869 of a Cypriot–Phoenician bilingual inscribed for King Milkiyaton of Idalion and Kition.

[𐠀𐠌𐠈𐠎𐠊𐠀.𐠀𐠊𐠀.𐠊𐠌𐠊.]𐠊𐠊𐠀.𐠊𐠌𐠊.𐠊𐠌𐠊

lmlk mlkytn [mlk kty wʔdly]

𐠋𐠎𐠈𐠊𐠎𐠀𐠊𐠀 · 𐠋𐠎𐠀𐠊𐠎 · 𐠊𐠀𐠊𐠎𐠈𐠀𐠊𐠀𐠈 · 𐠊𐠀𐠊𐠎𐠀𐠊𐠀

pa-si-le-wo-se mi-li-ki-ja-to-no-se ke-ti-o-ne ka-e-ta-li-o-ne

. . . basilewos milkijatonos ketion ka edalion . . .

The passage allowed Smith to isolate the names of the king and of the two cities, and a (correct) guess that the first word was the genitive of *basileus* 'king' allowed him to identify the language as Greek. The subsequent discovery of more material, including Greek–Greek bilinguals (with the *Koine* text in alphabetic Greek and the Cypriot dialect in syllabic script) served to further refine and complete the decipherment.

The Syllabary

The Cypriot syllabary is a purely syllabic script; there are no logograms. In contrast with the Cretan linear scripts, it is written from right to left (perhaps under Semitic influence). The inventory of signs can be found in Figure 4. The Cretan roots of the syllabary are evident from a number of sound-shape correspondences, as shown in Table 3.

Apart from the direction of writing, the Cypriot syllabary differs structurally from Linear B in the following points:

	a	*e*	*i*	*o*	*u*
∅	𐠀	𐠀	𐠀	𐠋	𐠊
j	𐠌			𐠎

w	𐠀	𐠀	𐠀	𐠋	
x/z	𐠋	𐠋		𐠋	
(g)	𐠀				

Figure 4 The Cypriot syllabary.

Table 3 Cypriot-Cretan shape-sound correspondences

Cypriot		*Linear B*	
lo	𐠈	*ro*	𐠈
na	𐠎	*na*	𐠎
pa	𐠈	*pa*	𐠈
po	𐠋	*po*	𐠋
sa	𐠊	*sa*	𐠊
se	𐠊	*se*	𐠊
ta	𐠈	*da*	𐠈
to	𐠈	*to*	𐠈

- The *d* series and *t* series have been merged.
- The *l/r* series of Linear B has been split into distinct *l* and *r* series.
- The labiovelars have been lost in Cypriot, as in all later Greek dialects, and the *q* series is therefore no longer required.

The first change makes sense considering that voiced, voiceless, and aspirated consonants are otherwise not distinguished in either Linear B or the Cypriot syllabary. In this context, the (localized) existence of a special sign to denote /ga/ in Cypriot is unexpected. An important difference is that the Cypriot spelling conventions require that all consonant clusters (except internal syllables ending in a nasal) be written in full. Thus, Linear B 𐠀𐠈𐠈𐠋 **a-to-ro-qo**, pronounced /ant^{h}ro:k^{w}os/ (nominative) or /ant^{h}ro:k^{w}on/ (accusative) corresponds to Cypriot 𐠊𐠋𐠈𐠊𐠋 **o-a-to-ro-po-se** /ho ant^{h}ro:pos/ or 𐠋𐠋𐠈𐠈𐠈 **to-na-to-po-ro-ne** /ton ant^{h}ro:pon/.

Anatolian (Luwian) Hieroglyphs

Anatolian hieroglyphs were in use in most of Anatolia and parts of modern Syria during most of the 2nd millennium B.C.E. and in the 1st millennium up to ca. 700 B.C.E. The early material from Hattusas and other centers of the Hittite Empire (largely inscribed on seals) makes heavy use of logograms, making it impossible to say in which language they were written: Most of the syllabograms are consistent with Luwian but Hittite cannot be excluded, and sometimes the signs are to be read using Hurrian sound values. The later texts (ca. 900–700), mainly inscriptions on rock and stone, but also some letters and records on lead strips, are from the 'Neo-Hittite' (Luwian) principalities of Southeastern Anatolia and northern Syria and are written in the Luwian language. A number of *pithoi* found at Altintepe use Anatolian hieroglyphs to write the Urartian language (a language related to Hurrian that was spoken around Lake Van in modern Armenia).

Decipherment

The first inscriptions were discovered in 1812 by J. L. Burckhardt in Syria. The connection with the Hittites, whose importance as the third major power in the ancient Near East could only have been guessed at by the references to them in the Old Testament texts but which had become clear after the decipherment of Egyptian hieroglyphics and Assyro–Babylonian cuneiform, was first established at the end of the 19th century by William Wright and Archibald Sayce, who were the first to use the term 'Hittite hieroglyphs' for the script. Sayce (1880) was also the first to make some progress with the decipherment by studying the *Tarkondemos* seal and other Hittite seals that contained brief texts in both cuneiform and hieroglyphs. Thus, he was able to identify the logograms for 'king' and 'land' and to identify some syllabograms. Similar analyses by Campbell Thomson (1913), based on identifying the names of kings, cities, and gods, led to the establishment of some more logographic and phonetic values.

With the discovery in 1906–1907 of the cuneiform archives of the Hittite Empire at Hattusas (Boğazköy, since 1936 Boğazkale) and the discovery by Bedřich Hrozný (1915) that they were largely written in an Indo–European language, Hittite (Nesian, Hitt. *nesili*), with other documents in the related Luwian language (Hitt. *luwili*), the decipherment of the 'Hittite hieroglyphs' entered its second phase. The language of the hieroglyphic inscriptions could now be checked against the documents in Hittite and Luwian, and in the 1930s substantial progress was made by a group of scholars, among them Piero Meriggi, Emil Forrer, I. J. Gelb, Helmuth Th. Bossert, Hans Gustav Güterbock, and Emmanuel Laroche. By the 1940s, many of the more common syllabic and logographic signs had been correctly identified, so that when the first substantial bilingual text (the Karatepe inscriptions in Phoenician and Hieroglyphic Luwian) was discovered in 1946 by Bossert, its impact was merely to confirm what had already been discovered the hard way. Laroche's *Les hiéroglyphes hittites* (1960) and Meriggi's *Hieroglyphisch-hethitisches Glossar* (1962) culminate this phase of the research. Since then, work on the reading and understanding of the Luwian hieroglyphic texts and their grammar has continued, and, in 1974, J. David Hawkins, Anna Morpurgo-Davies, and Günter Neumann, based in part on earlier research by Bossert, Hermann Mittelberger, and Mustafa Kalaç, reevaluated the readings of a small, but important, number of signs. They also established the convention to transcribe the ideograms and determinatives using Latin translations and suggested abandoning Sayce's old denomination 'Hittite hieroglyphs' in favor of the more accurate 'Luwian hieroglyphs.'

The Syllabary

For the syllabic signs, see Figure 5. For some common logograms, see Figure 6.

The inscriptions consist of horizontal rows, to be read in *boustrophedon* fashion, with the signs facing towards the beginning of the line, as in ancient Egyptian writing. The rows themselves are divided into 'panels' in which two or more signs are arranged vertically from top to bottom, although strict reading order is sometimes abandoned in favor of aesthetics, that is, to ensure that all available space is filled. There is a sign to mark a word-break (⟩|⟩), but it is not frequently used. The script is a mix of logograms, determinatives, and syllabic signs. As some of the signs do double duty as logogram and syllabogram, there is, as in Egyptian hieroglyphics, a special notation to mark the logographic use of a sign (it is put in

between 'quotes,' e.g.,)𐄀('foot'). The syllabic signs are mainly V or CV (open syllabary), although there are perhaps two VC signs and some others have a more complex CVC(V) reading. Unlike Linear B or Cypriot, there is a rather large number of homophonic signs (transcribed in Sumerological/Assyriological fashion as *ta*, *tá*, *tà*, *ta*$_4$, etc.). There is no polyphony as there is in cuneiform, in which a single sign can have multiple unrelated phonetic values, but, especially in the early texts, some of the signs can have an indeterminate vocalic value. In particular, the same sign can be used for C*a* and C*i* (more rarely also C*u*). In the later texts, there is a tendency to modify signs in order to mark the quality of the vowel explicitly (e.g., 2nd millennium: ↑ = *za/i*, 1st millennium: ↑ = *za*, ↑ = *zi*). Apart from the double underscore, the 'staff' sign LITUUS could probably also be used to modify the reading of a syllabogram (e.g., = /i/, = /ja/). However, the other uses of the LITUUS sign remain largely mysterious. Another way to modify the reading of syllabograms was by using ligatures. For instance, the sign <u(wa)> was

Figure 7 Acrophony in Luwian (after Zinko).

modified to <mu(wa)> by adding the four marks of the numeral *mawa* 'four.'

The vowels /*e*/ and /*o*/ are never marked separately and probably did not exist in the language. Long vowels (/*a:*/, /*i:*/, and /*u:*/) probably did exist but are left unmarked in the script (*plene* spellings such as -*tu-u* occur, but they are merely an aesthetic device to avoid gaps in the inscription). The script is also deficient in not marking the difference between voiced and voiceless stops, with the exception of the signs *ta₄* and *ta₅*, which always seem to stand for /da/. Crucially for a writing system that evolved by acrosyllabic interpretation of pictograms, the Luwian language (and Anatolian languages in general) did not distinguish the voicing of stops in initial position. The lack of initial /r/ in Anatolian also explains why the *r* series is so poorly represented in the script: There are a couple of signs for /ru/, but for /ra/, /ri/, as well as /r/ at the end of a syllable, the 'thorn' diacritic ◡ is used, which is not properly a letter but modifies the sign to which it is attached. In the most recent Luwian inscriptions, the 'thorn' takes the place of what was written earlier using signs of the *t* series, but this reflects a change in the language, namely the rhotacism of /d/ > /r/. As in the Aegean syllabaries, /n/ at the end of a syllable is always left unmarked:

DEUS-TONITRUS-**hu-za** /tarxunts/ '(the god) Tarḫunt'

Consonant clusters and final consonants are written using 'empty vowels,' and geminate consonants (assuming they existed in Luwian) are written as if they were single consonants. For evidence of the Luwian acrophonic origin of the script, see **Figure 7**.

The most radical change in the interpretation of the signs came with the joint article by Hawkins, Morpurgo-Davies, and Neumann in 1974. Meriggi and Laroche, in their fundamental works of the early 1960s, had established the values of the vowel signs as follows: ∩ = /a/, = /i/, and or = /u/. In addition to these, some other pure vowel signs were recognized (á = , à = , a_4 = , ì =). The variants with double underscores were tentatively thought to represent long vowels (ā = , ī = , $ā_3$ =), although other proposals had been made (e.g., Gelb suggested nasalized vowels). But, as Hawkins *et al.* showed, the true value of the sign ∩ was /i/, alternating with /ja/, the latter reading being distinguished in the 1st-millennium texts by writing it . This also implied that the signs and were not /i/ and /ī/ but, as Bossert and Kalaç had already suggested, /zi/ and /za/, respectively. The net result of these and other reevaluations of the readings was to bring the language lexically and morphologically closer to Cuneiform Luwian (CLuw.); for example, the demonstrative pronoun could now be read as *za-*, the plural endings as *-(n)zi* and *-(n)za* (the only equation that had to be given up was that of CLuw. *a-a-ja-* 'to make' with HLuw. **a-i-a-*, now to be read as *i-zi-ja-*, but this was a minor price to pay).

Ælfric (fl. 987–1010)

M Cummings, York University, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Recognized as the greatest Old English prose stylist, Ælfric is also the author of the first grammar in English. In 987 he went as master of novices to the monastery of Cernel (modern Cerne Abbas, Dorset), already in orders, and thus he was at least 30 years of age. He had been a pupil of the reforming Bishop Æthelwold in the school at Winchester. With his contemporary Wulfstan, Archbishop of York (obit. 1023), he was one of the two most prominent literary figures of the Benedictine Reform. His production of the *Catholic Homilies* belongs to the period 990–995, that of the *Lives of Saints* was no later than 998, and he became the first Abbot of Eynsham, near Oxford, in 1005.

His work in language education includes the grammar, a glossary, and the *Colloquy on the Occupations*. The first of these works is the *Excerptiones de arte grammatica anglice*, designed to introduce junior students to the Latin grammar. It is based on the *Excerptiones de Prisciano*, a Latin treatise of the 9th century, compiled from the 6th century *Institutiones grammaticae* of Priscian, and like it concentrates on Latin syllabification, graphology, phonology, parts of speech, and morphology. The *Glossary* is a compilation of Latin vocables with Old English glosses. The *Colloquy* is an imaginary Latin dialogue between a master and his pupils, who represent themselves as having various occupational roles, the ploughman, the huntsman, the fisherman, and so forth. Each describes the habits and rigors of the occupation, sometimes sympathetically.

Ælfric's other extant works include the *Catholic Homilies*; the *Lives of Saints*; a *De temporibus anni*; and a collection of letters, most notably one to the bishop of Sherborne, Wulfsige, and two to Archbishop Wulfstan, designed as expert responses to theological questions. His prose is remarkably lucid in comparison with that of some authors of the period. Parts of his work are rendered in a heightened style that has been called *rhythmic prose*, which in its metrical regularity shares some of the characteristics of Old English verse but is distinct from it. His work has long been taken as the exemplar of the Late West Saxon historical and regional dialect.

The *Catholic Homilies* were produced in two series that together comprise alternate English sermons for Sundays and saints' days. Like the grammar, however, they are based on a Latin exemplar, the late 8th century *Homiliary* of Paul the Deacon, which was created for reading in the monastic offices. The *Lives of Saints* are English versions of lives and martyrdoms for saints celebrated in the monastic liturgy, mainly taken from a 9th century Latin collection. The *De temporibus anni* inculcates the chronology necessary for the calculation of the Easter date.

Affixation

A Carstairs-McCarthy, University of Canterbury, Christchurch, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Definition

An affix is a bound morph that (1) is not a root and (2) is a constituent of a word rather than of a phrase or sentence. Some examples that follow illustrate the implications of (1) and (2). The next section surveys the kinds of affixation that occur, and the last sections discuss theoretical issues.

In most complex words, identifying a root (or roots, if the word is a compound) presents little difficulty. For example, in the words *misfortunes* and *premeditated*, the roots are clearly *fortune* and

medit- because these morphs make the most concrete and distinctive contributions to the meanings of these words; furthermore, *fortune* is free, as most English roots are. (The root of *premeditated* is *medit-*, not *meditate*, because *-ate* is a verb-forming affix that occurs also in *generate*, *vibrate*, and many other words.) Only rarely do we encounter a morph whose status seems unclear or dependent on context. One such example is `/fu:l/`, which might be considered the same morph in *fullness* (where it is a root) and *spoonful* (where it is an affix). These certainly have the same historical origin. However, most analysts of contemporary English prefer to distinguish three morphs: a root in *full* and *fullness*, a noun-forming affix in *spoonful*, and an adjective-forming affix in *peaceful* and *cheerful*. A similar problem is posed by some of the morphs indicating case in Hungarian nouns and pronouns. The bound morph *-nek* seems clearly to be an affix in when attached to *ember* 'person' in *embernek* 'to (a) person', but that is less clear in *nekem* 'to me', where it is attached to another bound morph *-em,* which normally means 'my.' The word form *nekem* thus arguably consists of two affixes with no root.

In *misfortunes* and *spoonful*, the nonroot morphs *mis-*, *-s,* and *-ful* are clearly parts of words rather than parts of phrases. But that is not so clearly true of the bound morphs *-'ll* and *-'s* in *she'll come tomorrow* and *the man next door's car.* These are generally classified as clitics (*see* **Clitics**) rather than affixes because what they are attached to grammatically is not a word (or part of a word) but a phrase: *come tomorrow* and *the man next door.* (Phonologically, *-'ll* is attached more closely to *she* than to *come tomorrow*, but that does not affect its grammatical status.) Clitics constitute a third kind of bound morph, alongside bound roots and affixes. Occupying a kind of no-man's-land between morphology and syntax, their analysis is controversial.

Types of Affix

Affixation is the process whereby an affix is attached to a base, which may be simple (as in *full*, the base to which *-ness* is attached to yield *fullness*), or complex (like *meditate*, the base to which *pre-* is attached to yield *premeditate*). Languages that make no use of affixation at all are hard to find. In Vietnamese, where most morphs are free, bound morphs with relatively abstract meanings such as 'not' or 'agent' appear in some complex words of Chinese origin (Nguyen, 1987). But these complex words are structurally just like others that are classified as compounds (containing only roots); besides, abstractness of meaning is not generally regarded as sufficient reason by itself to classify a bound morph as an affix. Vietnamese is thus arguably a language with no affixation.

Logically, an affix could be attached after, before, or inside its base. All these possibilities in fact occur, although not with equal frequency. Other morphological processes have been brought under the umbrella of affixation too, as will be illustrated.

Suffix

A suffix is an affix that follows its base. English examples so far presented are *-s* in *misfortunes*, *-ate* and *-(e)d* in *premeditated*, and *-ful* in *spoonful* and *cheerful*. In English, words with as many as three suffixes (e.g. *organ-iz-ation-al*, *profess-or-ship-s*, *authent-ic-at-ing*, *lead-er-less-ness*) are unusual. However, in a language such as Turkish, with an elaborate morphology that is almost entirely suffixal, much longer strings of suffixes are possible, as in the word transcribed phonemically at (1) (Lewis, 1967: xx):

(1) avrupa-li- laş-tir-il- amij-an-lar-
Europe-an become-CAUS-PASS unable-being-PL
dan-sin-iz
among-you-PL
'you are among those who cannot be Europeanized'

Here the root /avrupa/ 'Europe' is followed by 10 suffixes.

Words with similar long strings of morphs are characteristic of polysynthetic languages such as Inuktitut (Eskimo). In these languages, complex word forms often correspond in meaning and function to phrases and even sentences in other languages.

Prefix

A prefix is an affix that precedes its base. English examples so far presented are *mis-* in *misfortunes* and *pre-* in *premeditated*. In English, all prefixes are derivational; thus, *un-* in *unhappy*, *de-* in *decontaminate*, *counter-* in *countersignature,* and so on create new lexemes rather than inflected forms of *happy*, *contaminate,* and *signature*. In Bantu languages such as Zulu, on the other hand, many prefixes are inflectional; on verbs, they can signal tense, polarity, and agreement with both subject and object, as in (2) and (3) (Doke, 1973; Rycroft and Ngcobo, 1979):

(2) si- ya- zi- fún- a izin- cwâdí
we- PRES- them- want- POSITIVE PL. 10- book
'we want the books'

(3) a- sí- zi- fún- i izin- cwâdí
not- we- them- want- NEG PL.10- book
'we don't want the books'

Here, the verbal prefix *zi-* agrees in gender (or class) and number with the noun form *izincwâdí*, whose

class (10) and number (plural) are indicated by the prefix *izin-*. The subject 'we' is indicated by a prefix *si-*. The acute accent indicates a high tone and the circumflex a falling tone; unmarked syllables have a low tone.

Circumfix

Whereas the terms prefix and suffix are well established, the term circumfix has less currency. This is at least partly because the phenomenon itself is less common and less straightforward to identify. A circumfix is a combination of a prefix and a suffix that cooccur (at least with bases of specified type) to fulfill a joint function. One example is the Italian affixal combination *in-…-are,* which can derive infinitive forms of verbs meaning 'to become X' from adjective roots, for example, *invecchiare* 'to age' from *vecchio* (root *vecchi-*) 'old.' A reason for calling this a circumfix, rather than just a combination of a prefix and a suffix, is that there is at first sight no basis in Italian morphology for either choosing *invecchi-* as a base to which *-are* is suffixed or choosing *-vecchiare* as a base on to which *in-* is prefixed. (For discussion, see Scalise, 1984: 146–150.)

Other candidates for circumfix status are *ge-…-t* and *ge-…-en* as markers of the past participle in German verbs, for example, *gereist* from *reisen* 'to travel' and *gebrochen* from *brechen* 'to break.' The case is not entirely solid, however. That is because, although one or other of the suffixes *-t* or *-en* appears on all German past participle forms, the prefix *ge-* is absent from those with a inseparable prefix, for example, *verreist* from *verreisen* 'to go on a journey', and also from verbs whose first syllable does not have primary stress, for example, *telefoniert* 'telephoned' from *telefonieren* 'to telephone' (primary stress is on the syllable *-nie-)*. In Dutch, the case for circumfixal status for the corresponding combinations *ge-…-d* and *ge-…-en* seems stronger because, although *ge-* is incompatible with inseparable prefixes (as in German), it is compatible with verbs that lack initial stress, for example, *getelefoneerd* 'telephoned' from *telefoneren*. Even here, however, the fact that *-d* can appear without *ge-* points toward treating them as separate affixes.

These examples illustrate the difficulty of establishing that a circumfixal analysis is the only one possible for a given body of data. In some models of morphological structure, circumfixal analyses are ruled out in principle. If the elements of a purported circumfix are treated instead as distinct affixes, then they constitute an example of multiple synonymous affixation.

An alternative term for circumfix, sometimes encountered, is ambifix. The phenomenon of circumfixation is sometimes called parasynthesis.

Infix

An infix is an affix that is inserted inside its base. An example is the Tagalog affix *-um-*, which on verbs indicates that an accompanying trigger noun phrase denotes an actor (Schachter, 1987), as in *tumakbo* from the base *takbo* 'run.' (The corresponding form from *abot* 'reach for' is *umabot*, where it looks as if *-um-* is prefixed rather than infixed; but this is only because the initial glottal stop of /ʔabot/ and /ʔumabot/ is not represented in the spelling.)

In recent years, infixation has attracted a considerable amount of interest because it is typologically unusual and it seems somehow unnatural for an affix to interrupt its base rather than be concatenated with it. Various suggestions have therefore been made about limits on the circumstances in which infixation can occur. With complex words as bases, it has been suggested that infixes may occupy four morphologically defined positions: before or after the root, after the initial morph, and before the final morph (Anderson, 1993). A suggested instance of morphs being infixed so as to appear before a final morph occurs in Icelandic. There, tense and person-number suffixes are attached to verb roots. Therefore they always precede a verb-final suffix *-st* (historically derived from a reflexive pronoun), whose main current function is passive or reflexive, for example, *köll-uðum-st* '(we) were called'.

According to an approach developed in Optimality Theory (Kager, 1999), infixation is often if not always a phonological rather than a morphological phenomenon. That is, an infix is an affix that is inserted close to, rather than at, one end of its base so as to promote observance of phonological well-formedness constraints. Thus, in the Tagalog word form *t-um-akbo* 'run' the affix *um-* is not prefixed to the base *takbo* but infixed after the initial consonant so that its consonant [m] can constitute the onset of a syllable [ma] rather than the coda of a syllable [um]. This is because a word form with the syllabification [$tu_\sigma mak_\sigma$-bo_σ], with only one consonant [k] in coda position, is preferable in Tagalog to a word form such as [$um_\sigma tak_\sigma bo_\sigma$], with two consonants [m] and [k] in coda position.

Suprafix

Suprafix is a term sometimes used for a morphological process involving suprasegmental factors such as changes in stress or pitch. For example, in English, the noun *tórment* and the verb *tormént* are distinguished by the position of the stress. Assuming that the noun is derived from the verb, we might analyze it as involving a suprafix of first-syllable stress, manifested in a substantial class of nouns including *prótest*,

tránsfer, and *pérmit*. Similarly, in Attic Greek, in some nominal and adjectival compounds with a verbal second element, this verbal element receives an active interpretation if it carries a high pitch accent (e.g. *patro-któnos* 'father-killer, parricide') but a passive interpretation if the high pitch is on the first element instead (*patró-ktonos* 'killed by his/her father') (Vendryès, 1945: 195). If stress and pitch are seen as lying on a distinct phonological tier from segmental features (*see* **Autosegmental Phonology**), such changes can be seen as involving an affix whose sole phonological content lies on that tier.

The suprafix notion can be extended to include all morphemes that are represented on separate autosegmental tiers. This has been proposed as one way of analyzing the vocalic alternations that are prominent in Semitic languages such as Arabic and Hebrew (*see* **Internal Modification**). On the other hand, we may argue that this brings under the umbrella of affixation phenomena so diverse as to render the term 'affix' virtually synonymous with 'morphological process,' obscuring real differences between different processes.

Relative Frequency of Different Types of Affixes

Suprafixation is common; on the other hand, it is doubtful whether this should be classified as affixation at all, for the reason previously given. Infixation has a peculiarly uneven incidence – in many of the languages that exhibit it (e.g., Austronesian languages such as Tagalog), it is used widely, but in the vast majority of languages it is not used at all. Clear examples of circumfixation are rare or nonexistent. That leaves prefixation and suffixation, which between them account for the vast bulk of affixation. Of these two, suffixation is by far the commoner. Many languages use suffixation only, but relatively few make exclusive or predominant use of prefixation (although Central Khmer (Cambodian) and other Mon-Khmer languages are often cited as examples).

It is conceivable that the predominance of suffixation is a historical accident, with nothing in grammatical or psycholinguistic theory to explain it. But it seems more likely that it has to do with the way in which complex words are analyzed by the brain. There is evidence that it helps to identify the root of a word at an early stage in its processing. If that is so, then prefixes, which delay the appearance of the root, will be disfavored (Cutler *et al.,* 1985).

Affix Order and Morphological Structure

Derivational affixes usually appear closer to the root than inflectional ones. For example, in the English word *sing-er-s*, the inflectional suffix *-s* follows the derivational suffix *-er*. Plausible reasons for this are not hard to find. Derivational affixes often change word class (as *-er* does here, converting the verb *sing* into a noun), and it would be surprising if in this instance an inflectional affix appropriate to nouns were attached to the verbal base *sing* before such conversion had taken place, so as to yield a hypothetical form **sing-s-er*. (It is true, however, that a form such as **sing-s-er* could in principle be formed by infixing *-s-* between the root and the affix of *sing-er*.)

This objection does not apply with such force if the derivational affix in question does not change word class. The actual plural of *book-let* is *book-let-s*, but in a hypothetical form *book-s-let* the base *book* to which the inflectional affix is added is at least a noun, hence suitable for pluralization by means of this affix, unlike the verbal base *sing*. So it is not surprising to find that in some languages derivational affixes that do not change word class, such as diminutive affixes, can indeed sometimes appear outside inflectional affixes (Stump, 1993). Examples involving derived verbs can be found in Classical Attic Greek and Georgian. In those languages, derivational prefixes that precede verb roots can be separated from the root by inflectional material, as illustrated in the Greek examples (4) and (5).

(4)	syn-	tatt-	omen
	together-	arrange-	1.PL

'we are drawing up' (e.g., an army for battle)

(5)	syn-	e-	tatt-	omen
	together-	IMPERF-	arrange-	1.PL

'we were drawing up'

The inflectional prefix *e-*, used in forming the imperfect tense (which has a past progressive meaning), is prefixed to a verb root as its base, as in *e-tatt-omen* 'we were arranging' versus *tatt-omen* 'we are arranging.' But in (5) this *e-* intervenes between the root and the derivational prefix *syn-* 'together.' (This prefix is related to the preposition *syn* 'with,' so they arguably constitute another instance of a morph that is sometimes an affix and sometimes a root.)

The attachment of inflectional affixes outside morphological ones seems to suggest that complex words have a nested hierarchical organization like this (in a purely suffixing language): [[[root(s)] derivational affixes] inflectional affixes]. (In a language with some prefixation, the linear order will not be so consistent, but the nesting will be similar.) Many morphologists have argued that this kind of hierarchical organization works in such a way that for every affix there is a layer of structure in which that affix and the base to which it is attached are sisters. Thus the words *lead-er-less-ness* and *pre-medit-ate-d* are not just strings of morphs but have a structure as follows:

[[[lead] -er] -less] -ness], [[pre- [[medit-] -at-]] -ed]. This kind of binary branching, or nesting, is characteristic of syntax too, at least in configurational languages. It is not surprising, therefore, that a fair number of morphologists have argued that morphological and syntactic structure are basically similar (Selkirk, 1982; Lieber, 1992; and, with qualifications, Halle and Marantz, 1993). Such a view is broadly compatible with how complex words are structured in those languages where affixation predominates over other modes of morphological expression and where each affix has a clear-cut and distinct meaning or function. This theoretical approach therefore provides an impetus for attempts to subsume under affixation superficially nonaffixal processes (*see* **Internal Modification** and previous discussion).

Morphologists differ on how far other supposed parallels between morphology and syntax should be pressed. One term that has a respectable pedigree of application in both domains is head. In syntax, uncontroversially, the head of a noun phrase is a noun, the head of a verb phrase is a verb, and so on, the nonhead material being modifiers of various kinds such as complements, adjuncts, and specifiers. However, what constitutes the head of a complex word is less clear (Zwicky, 1985; Bauer, 1990). According to one view, the head is the root, so the head of *booklet* and *singer* are *book* and *sing,* respectively. This entails that the head of a word may belong to a different word class than the word itself (as *sing* does in relation to *singer*). A more influential view in recent years has been that the head is the rightmost element (whether root or affix), which is often the one that determines the word class of the whole word (see Williams, 1981, on the Right-Hand Head Rule). The head of *singer* is then *-er*, which not only contributes the meaning 'agent' but also determines the word's status as a noun. This also implies, however, that the head of the Greek verb form *syn-e-tatt-omen* in (4) is not the verbal root *tatt*-but the person-number suffix-*omen*; and it implies that the head of the English verb *enthrone* is not the prefix *en-* (which has a verb-forming role also in *empower* and *enrich*) but the root *throne*, which is a noun. Some linguists have consequently argued that different parts of a word may count as the head for different purposes; but then it becomes unclear how helpful this notion is.

The view of word structure as basically similar to sentence structure is less easy to reconcile with internal modification and with phenomena of the kind outlined in the next section. Therefore, those morphologists who draw attention to such phenomena tend to reject the view of morphological structure as universally hierarchical (Anderson, 1992; Stump, 2001).

As regards the order in which affixes are attached within the broad domains of derivation and affixation, Bybee (1985) has argued that a principle of relevance applies: An affix A will be closer to the root than an affix B if affix A's contribution to the meaning of the word more directly affects the lexical content of the root than affix B's does. It is for this reason, she says, that aspect and tense markers on verbs are generally closer to the root than person and number markers are (for example).

Multiple Synonymous Affixation

Consider again the Zulu examples at (2) and (3). Example (3) is the negative counterpart of (2), so it is natural to expect to find in it a morph meaning 'not.' Indeed there is one: the initial prefix *a-* on the verb form. However, negativity is also signaled by a suffix *-i*, on the basis of which, in the corresponding active verb form, the final *-a* is analyzed as a suffix meaning 'positive.' In the verb form *a-sí-zi-fún-i* 'we do not want them,' there are thus two synonymous affixes. But the signaling of 'negative' does not end there. In (3), the tense marker *-ya-* 'present' is missing, so it could be construed as marking not just 'present' but 'present active'; and the prefix *si-*, which bears a low tone in (2), has a high tone in (3) (indicated by an acute accent). It is usual in Zulu, in fact, for corresponding positive and negative verb forms to differ tonally.

There is nothing freakish about this Zulu example. A similar point can be made by reference to the Greek examples at (4) and (5), slightly adapted:

(6)	syn-	tatt-	o:
	together-	arrange-	1.SG
	'I am drawing up' (e.g., an army for battle)		

(7)	syn-	e-	tatt-	on
	together-	IMPERF-	arrange-	1.SG
	'I was drawing up'			

Here, first-person singular forms replace first-person plural ones. But in (7) the tense contrast with (6) is signaled not merely by the prefix *e-* but also by the choice of *-on* rather than *-o*: as the first-person singular suffix. However, we cannot simply ascribe to *-on* the combination of meanings 'first-person singular imperfect' because *-o*: and *-on* (and similar pairs of affixes for other person-number combinations) are distributed around the verbal paradigm in a fashion that defies any such straightforward correlation.

The terms multiple exponence and extended exponence have been applied to situations such as this, in which one meaning or function (such as 'negative' or 'imperfect') is realized in more than one place in a

word form, not always affixally. Often, as here, this exponence overlaps with that of some other meaning or function. Because such situations of many-to-many form-meaning relationships are common, some morphologists (e.g., Anderson, 1992; Stump, 2001) argue that it is misleading to assign to affixation a central place in morphological theory and deny that complex words have a syntaxlike structure (*see* **A-Morphous Morphology**).

Diachronic Issues

At the beginning of this article, we encountered an affix that is historically derived from a free form, namely *-ful* as in *spoonful* and *peaceful*. The passive-reflexive suffix *-st* of Icelandic, also discussed previously, is also clearly derived from a free form, a reflexive pronoun *sig* or *sik*. The suffix *-st* illustrates phonological reduction through the loss of a vowel (and also a change in the place of articulation of the last consonant). In the modern peninsular Scandinavian languages Norwegian, Swedish, and Danish, this suffix is further reduced to *-s*. This illustrates one aspect of a widespread kind of historical change often called grammaticalization or grammaticization, the process whereby free forms with lexical content become clitics or affixes with derivational or grammatical functions (Hopper and Traugott, 2003).

Could this be the way in which all affixes originate, not just some? This view has been widely held. But, if it is correct, it has implications not just for the contemporary human capacity for language but also for the origin of that capacity. The implication is that the existence of morphology calls for explanation in a way that the existence of syntax does not and that this explanation lies in saying that, even if morphology and syntax are today distinct, all affixes originated as items whose behavior was to be accounted for syntactically, not morphologically (Comrie, 1992). A radical alternative is the suggestion that regular alternations in the shape of morphs (*see* **Internal Modification**) may have originated for phonological reasons, thus establishing morphology as a mode of grammatical organization quite independent of syntax and perhaps even historically prior to it (Carstairs-McCarthy, 2005). Whether or not this is correct, it seems certain that our understanding of the relationship of affixation (and morphology in general) to syntax will benefit from research on the biological basis of the language capacity.

Main Language Families

In this rugged, thinly populated region much of the population is nomadic and therefore languages are not always discretely distributed. Also surprising relics and pockets exist. Although mainly an Indo-European speech area, Altaic impinges along the Oxus plain in the north. Of the former, Pashto spans the country east to west across the center, bounded by Persian (Farsi) (called locally Dari or Tadjik (Tajiki)) to the north and Baluchi (Balochi) to the south, while a wedge of Dardic, Nuristani, and Pamir languages occurs from Kabul northeastward to the Chinese frontier, and Ormuri and Parachi are found in islands eastward. Of the latter, Uzbek, Turkoman (Turkmen), and Khorasani Turkish overlap with Persian (Farsi) on the northern plain, and a dialect of Mongolian is spoken south of Herat. Semitic is represented by outlying pockets of Central Asian Arabic in four villages on the Oxus plain, while pockets of the Dravidian Brahui language, which has infiltrated from Pakistan, occur within the Baluchi (Balochi) area to the south. The main languages have coexisted for a long period and much mutual assimilation of phonology and lexis has occurred. In the north, for instance, *mayda* 'small,' *māldār* 'nomadic pastoralist,' and *qūš* 'migrate' are shared by Pashto, Tadjik (Tajiki), Uzbek and Arabic. Here as in Iran language, racial origin, and political grouping do not always correspond. Thus the Mongolian-descended Hazaras speak Persian (Farsi), much of the 'Arab' population speaks Tadjik (Tajiki) or Uzbek, and many Pathans are of Dardic racial origin. Conversely language is an important correlate of tribal affiliation among Pathans and Baluchis and the assimilation of ex-Pathan elements to Baluchi tribal units has resulted in the encroachment of Baluchi (Balochi) northward into Pashto territory. Similarly the Dravidian-speaking Brahuis nomadize within the Baluchi area and are organized along Baluchi tribal lines. The main languages are part of larger groups outside Afghanistan and result from incursion into the area. Pashto spreads east and south into Pakistan around Peshawar and Quetta, Persian (Farsi) spreads west and north to Iran and Tajikistan, while Baluchi (Balochi) spreads south to Baluchistan. All of these have written forms using the Arabic script. The smaller relic languages of the Dardic, Nuristani and Pamir groups probably covered larger areas in earlier times. Partial bi- or multilingualism is the norm in many areas and the similarity of phonology and great dialect diversity means that minority languages can exist undetected for long periods. Therefore new languages may yet await discovery.

Minor Indo-European Languages

Afghanistan is a gold mine of unwritten Indo-European relics of a type transitional between Indian and Iranian which have borrowed freely from both groups. Although often spoken by only small numbers of people they are sufficiently different to be termed languages rather than dialects. Ormuri and Parachi in the east belong to the southeast Iranian group. Indic languages include Jatti or Gypsy (Jakati) and Gunjuri. The rest are found in the mountainous region stretching from Kabul northeastward to the Pamirs in the Wakhan corridor, which separates Pakistan from Tajikistan. Just to the northeast the Dardic group includes Pashai (Pashayi), Gawarbati (Gawar-Bati), Ningalami, Savi, Wotapuri, and Tirahi. Beyond them the languages of Nuristan (çi-devant Kafiristan from *kāfir* 'unbeliever', the population being pagan until recently) include Kati, Waigali, Ashkuni (Ashkun), Prasuni, and Tregami. Beyond them still the Pamir group includes Ishkashemi-Sanglechi (Sanglechi-Ishkashimi), Shughni-Roshani, Mundji (Munji), and Wakhi. The region resembles other mountainous regions such as the Caucasus and the western mountain belt of North America in its linguistic diversity and high incidence of relic and outlying forms. Many of these languages also exhibit types of ergative systems characteristic of relic areas. The present political boundaries narrowly miss including Burushaski, a language of the Pamirs to the south of the Wakhan corridor bordering on Wakhi, unrelated to any other known tongue.

Africa as a Linguistic Area

B Heine, Institut für Afrikanistik, Universität zu Köln, Köln, Germany

© 2006 Elsevier Ltd. All rights reserved.

On Linguistic Areas

A number of different definitions of linguistic areas have been proposed; what is common to most of them are the following characteristics:

1. There are a number of languages spoken in one and the same general area.
2. The languages share a set of linguistic features whose presence can be explained with reference to neither genetic relationship, drift, universal constraints on language structure or language development, nor to chance.
3. This set of features is not found in languages outside the area.
4. On account of (2), the presence of these features must be the result of language contact.

Among the linguistic areas (or Sprachbunds) that have been proposed, perhaps the most widely recognized are the Balkans and Meso-America. The African continent has been said to form a linguistic area, but so far there is no conclusive evidence to substantiate this statement.

Earlier Work

While there were a number of studies on areal relationship in Africa in the earlier history of African linguistics, Greenberg (1959) constitutes the first substantial contribution to this field. In an attempt to isolate areal patterns both within Africa and separating Africa from other regions of the world, he proposed a number of what he called 'special' features of African languages. The properties listed by Greenberg include in particular a number of lexical polysemies, such as the use of the same term for 'meat' and '(wild) animal,' the use of the same term for 'eat,' 'conquer,' 'capture a piece in a game,' and 'have sexual intercourse,' and the use of a noun for 'child' as a diminutive or of 'child of tree' to denote 'fruit of tree.' Another noteworthy contribution to areal relationship within Africa appeared in 1959: Larochette (1959) presented a catalog of linguistic properties characteristic of Congolese Bantu (Kikongo [Kituba], Luba, and Mongo [Mongo-Nkundu]), an Ubangi language (Zande), and a Central Sudanic language (Mangbetu), but many of the properties proposed by him can also be found in other regions and genetic groupings of Africa. A catalog of properties characterizing African languages was also proposed by Welmers (1974) and Gregersen (1977). Building on the work of Greenberg (1959) and Larochette (1959), Meeussen (1975) proposed an impressive list of what he called 'Africanisms,' that is, phonological, morphological, syntactic, and lexical properties widely found in African languages across genetic boundaries.

Another seminal publication on areal relationship was published by Greenberg in 1983. Noting that there are no areal characteristics found everywhere in Africa but nowhere else, he proceeded to define areal properties "as those which are either exclusive to Africa, though not found everywhere within it, or those which are especially common in Africa although not confined to that continent" (1983: 3). As an example of the former, he mentioned clicks; as instances of the latter, he discussed in some detail the following four properties: (1) coarticulated

Africa as a Linguistic Area

B Heine, Institut für Afrikanistik, Universität zu Köln, Köln, Germany

© 2006 Elsevier Ltd. All rights reserved.

On Linguistic Areas

A number of different definitions of linguistic areas have been proposed; what is common to most of them are the following characteristics:

1. There are a number of languages spoken in one and the same general area.
2. The languages share a set of linguistic features whose presence can be explained with reference to neither genetic relationship, drift, universal constraints on language structure or language development, nor to chance.
3. This set of features is not found in languages outside the area.
4. On account of (2), the presence of these features must be the result of language contact.

Among the linguistic areas (or Sprachbunds) that have been proposed, perhaps the most widely recognized are the Balkans and Meso-America. The African continent has been said to form a linguistic area, but so far there is no conclusive evidence to substantiate this statement.

Earlier Work

While there were a number of studies on areal relationship in Africa in the earlier history of African linguistics, Greenberg (1959) constitutes the first substantial contribution to this field. In an attempt to isolate areal patterns both within Africa and separating Africa from other regions of the world, he proposed a number of what he called 'special' features of African languages. The properties listed by Greenberg include in particular a number of lexical polysemies, such as the use of the same term for 'meat' and '(wild) animal,' the use of the same term for 'eat,' 'conquer,' 'capture a piece in a game,' and 'have sexual intercourse,' and the use of a noun for 'child' as a diminutive or of 'child of tree' to denote 'fruit of tree.' Another noteworthy contribution to areal relationship within Africa appeared in 1959: Larochette (1959) presented a catalog of linguistic properties characteristic of Congolese Bantu (Kikongo [Kituba], Luba, and Mongo [Mongo-Nkundu]), an Ubangi language (Zande), and a Central Sudanic language (Mangbetu), but many of the properties proposed by him can also be found in other regions and genetic groupings of Africa. A catalog of properties characterizing African languages was also proposed by Welmers (1974) and Gregersen (1977). Building on the work of Greenberg (1959) and Larochette (1959), Meeussen (1975) proposed an impressive list of what he called 'Africanisms,' that is, phonological, morphological, syntactic, and lexical properties widely found in African languages across genetic boundaries.

Another seminal publication on areal relationship was published by Greenberg in 1983. Noting that there are no areal characteristics found everywhere in Africa but nowhere else, he proceeded to define areal properties "as those which are either exclusive to Africa, though not found everywhere within it, or those which are especially common in Africa although not confined to that continent" (1983: 3). As an example of the former, he mentioned clicks; as instances of the latter, he discussed in some detail the following four properties: (1) coarticulated

Table 1 Relative frequency of occurrence of 11 typological properties in African languages[a]

Properties used as criteria	*Number of languages having that property*	*Percentage of all languages*
1. Labiovelar stops	39	39.4
2. Implosive stops	36	36.4
3. Lexical and/or grammatical tones	80	80.8
4. ATR-based vowel harmony	39	39.4
5. Verbal derivational suffixes (passive, causative, benefactive, etc.)	76	76.7
6. Nominal modifiers follow the noun	89	89.9
7. Semantic polysemy 'drink/pull, smoke'	74	74.7
8. Semantic polysemy 'hear/see, understand'	72	72.7
9. Semantic polysemy 'animal, meat'	40	40.4
10. Comparative constructions based on the schema [X is big defeats/surpasses/ passes Y]	82	82.8
11. Noun 'child' used productively to express diminutive meaning	50	50.5

[a]Sample: 99 languages. Parameters 3, 7, and 8 have two options; if one of the options applies, this is taken as positive evidence that the relevant property is present.

labiovelar stops, (2) labiodental flaps, (3) the use of a verb meaning 'to surpass' to express comparison, and (4) a single term meaning both 'meat' and '(wild) animal.' He demonstrated that these four properties occur across genetic boundaries and, hence, are suggestive of being Pan-African traits, especially since they are rarely found outside Africa.

Greenberg (1983) went on to reconstruct the history of these properties by studying their genetic distribution. He hypothesized that (1), (3), and (4) are ultimately of Niger-Kordofanian origin, even though they are widely found in other African families, in particular in Nilo-Saharan languages. For (2), however, he did not find conclusive evidence for reconstruction, suggesting that it may not have had a single origin but rather that it arose in the area of the Central Sudanic languages of Nilo-Saharan and the Adamawa-Ubangi languages of Niger-Congo.

Search for areal properties across Africa is associated not the least with creole linguistics. In an attempt to establish whether, or to what extent, the European-based pidgins and creoles on both sides of the Atlantic Ocean have been shaped by African languages, students of creoles pointed out a number of properties that are of wider distribution in Africa, perhaps the most detailed study being Gilman (1986).

Table 2 Distribution of 11 typological properties according to major world regions[a]

Region	*Total of languages*	*Total of properties*	*Average number of properties per language*
Europe	10	11	1.1
Asia	8	21	2.6
Australia/ Oceania	12	37	3.0
The Americas	14	48	3.4
Africa	99	669	6.8
Pidgins and creoles	6	14	2.3
All regions	*149*		

[a]Sample: 99 African and 50 non-African languages.

Pan-African Properties

The term 'Pan-African properties' refers to linguistic properties that are (1) common in Africa but clearly less common elsewhere, (2) found at least to some extent in all major geographical regions of Africa south of the Sahara, and (3) found in two or more of the four African language families. The following catalog of selected properties is based on previous work on this subject (especially Greenberg, 1959, 1983; Larochette, 1959; Meeussen, 1975; Gilman, 1986).

A general phonological property that has been pointed out by a number of students of African languages is the preponderance of open syllables and an avoidance of consonant clusters and diphthongs. Furthermore, tone as a distinctive unit is characteristic of the majority of African languages, in most cases on both the lexical and grammatical levels.

Ignoring click consonants, which are restricted to southern Africa and three languages in East Africa (Sandawe, Hadza, and Dahalo), there are a number of consonant types that are widespread in Africa but uncommon elsewhere. This applies among others to coarticulated labiovelar stops, (especially *kp* and *gb*), which occur mainly in a broad geographical belt from the western Atlantic to the Nile-Congo divide. Perhaps even more characteristic are labiodental flaps, produced by the lower lip striking the upper teeth; although restricted to relatively few languages, they are found in all families except Khoisan. A third type of consonants that is widespread in Africa but rarely found outside Africa can be seen in voiced implosive stops.

Figure 1 An isopleth sketch map of Africa based on 11 properties (sample: 99 languages).

In their arrangement of words, African languages of all four families exhibit a number of general characteristics such as the following: While on a worldwide level languages having a verb-final syntax (SOV) appear to be the most numerous, in Africa there is a preponderance of languages having subject-verb-object (SVO) as their basic order: Roughly 71% of all African languages exhibit this order. Furthermore, the placement of nominal modifiers after the head noun appears to be more widespread in Africa than in most other parts of the world. Thus, in Heine's (1976: 23) sample of 300 African languages, demonstrative attributes are placed after the noun in 85%, adjectives in 88%, and numerals in 91% of all languages.

Logophoric marking appears to constitute a specifically African construction type. Logophoric pronouns indicate coreference of a nominal in the nondirect quote to the speaker encoded in the accompanying quotative construction, as opposed to its noncoreference indicated by an unmarked pronominal device (concerning the areal distribution of these pronouns, see Güldemann, 2003).

Perhaps the most conspicuous area where one might expect to find Pan-African properties can be seen in lexical and grammatical polysemies. A number of examples of polysemy, such as 'meat'/'animal,' 'eat'/'conquer,' and so on, were mentioned earlier. Furthermore, there are some grammaticalization processes that are common in Africa but rare elsewhere, examples being the grammaticalization of body parts for 'stomach/belly' to spatial concepts for 'in(side),' or of verbs meaning 'surpass,' 'defeat,' or 'pass' to a standard marker of comparison (Heine, 1997: 126–129).

Quantitative Evidence

Being aware that for many of the Pan-African properties that have been discussed in the relevant literature there is only sketchy cross-linguistic information, Heine and Zelealem (2003) use a quantitative approach to determine whether Africa can be defined as a linguistic area. For each of the 149 languages of their sample, of which 99 are African languages and 50 are languages from other continents, they apply 11 criteria that have figured in previous discussions on the areal status of African languages. The criteria and main results of their African survey are listed in Table 1, and those of their worldwide sample in Table 2. What Table 2 suggests is the following:

1. Africa clearly stands out against other regions of the world in having on average 6.8 of the 11

properties, while in other regions clearly lower figures are found.
2. Outside Africa, no language has been found to have as many as five properties, while African languages have between 5 and 10 properties.

Isopleth Mapping

To study the internal structure of linguistic areas, isopleth mapping has been employed in linguistic areas such as South Asia (Masica, 1976), the Balkans (van der Auwera, 1998), and Meso-America (van der Auwera, 1998). Isopleth maps are designed on the basis of the relative number of features that languages of a linguistic area share: languages having the same number of properties, irrespective of which these properties are, are assigned to the same isopleth and, depending on how many properties are found in a given language, the relative position of that language within the linguistic area can be determined.

Applying isopleth mapping to Africa yields the following results: The most inclusive languages, having nine or more properties, are found in West Africa, including both Niger-Congo and Afro-Asiatic languages. A secondary isopleth center is found in the Cameroon–Central Africa area, where up to nine properties are found. Clearly less central are languages farther to the west and south, that is, Atlantic and Mande languages on the one hand, and Bantu languages on the other, where around six properties are found. Peripheral Africa consists of the Ethiopian Highlands (*see* **Ethiopia as a Linguistic Area**) and northern (Berber) Africa, where less than five properties are found. Figure 1 is based on an attempt to reduce the complex quantitative data to an isopleth map.

Conclusion

While there is no linguistic property that is common to all of the 2000-plus African languages, it seems possible on the basis of the quantitative data presented to define Africa as a linguistic area: African languages exhibit significantly more of the 11 properties listed in Table 1 than non-African languages do, and it is possible to predict with a high degree of probability that if there is some language that possesses more than five of these 11 properties, then this must be an African language. Not all of the properties, however, are characteristic of Africa only; some are equally common in other parts of the world.

African Linguistics: History

B Heine, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The first grammar of an African language appeared in 1659, when the Italian Capuchin Giacinto Brusciotto published a 98-page work on the Bantu language Kikongo (Kongo). As a distinct field, however, African linguistics developed only in the 19th century, when European missionaries studied African languages in some detail. By the end of that century there was a wealth of grammatical descriptions and dictionaries of African languages, some of which are still reference works today. Salient typological properties of African languages, such as complex tone structures and noun class systems, were identified and described in these works.

Comparative work also began in the 19th century; the first major genetic classification of African languages was published in 1854 by Sigismund Koelle. This classification served as a basis for later classifications by the Egyptologist Richard Lepsius in 1880 and, around the turn of the century, the German missionaries Carl Meinhof and Diedrich Westermann. The latter two became the leading figures of African linguistics, establishing African linguistics as an academic discipline. Meinhof and Westermann classified African languages into three major stocks: the 'Hamitic' languages of northern and northeastern Africa, the 'Sudanic' languages (*Sudansprachen*), spoken in a broad belt extending from Senegal in the west to Ethiopia in the east, and the Bantu languages of the southern half of Africa. This classification was based to quite some extent on 19th century language typology, in that the 'Hamitic' languages were said to belong to the inflectional type, whereas the Bantu languages were classified as agglutinating and the 'Sudanic' languages as isolating in structure.

Comparative African linguistics entered a new era when Joseph Greenberg (1963) proposed an alternative genetic classification. Pre-Greenbergian comparative African linguistics had suffered from the fact that no systematic distinction between different kinds of relationship was made, that is, it remained for the most part unclear whether the linguistic classifications proposed were intended to be genetically, typologically, or areally defined or, more commonly, were an amalgamation of all three kinds of relationship. According to Greenberg, the languages of Africa can be divided exhaustively into four families (or phyla): Niger-Kordofanian (including Niger-Congo), Afroasiatic, Nilo-Saharan, and Khoisan. Apart from minor revisions, this classification is now generally accepted, even if the evidence for the genetic unity of the last two families is not entirely satisfactory.

The question of areal relationship among African languages has been raised in a number of works, but so far no major results have emerged, apart from the fact that the Ethio-Eritrean highland region of northeastern Africa stands out as a linguistic area.

There is little information on the role of language in society in early studies of African linguistics. It is only since the 1960s, when the majority of African states attained their independence, that an interest in problems relating to multilingualism, language policy, etc. arose, resulting in a wide range of studies devoted to sociolinguistic problems of the African continent.

African Lexicography

R H Gouws, University of Stellenbosch, Stellenbosch, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article focuses on only a few aspects of the current state of affairs in lexicography on the African continent. The emphasis is not on a comprehensive account of all the lexicographic activities, but rather on a few topics portraying some significant changes and developments in African lexicography.

Scholarly Work Reflecting on Some Lexicographic Activities in Africa

Hartmann (1990a), a publication resulting from a workshop hosted at Exeter in March 1989 by the Dictionary Research Unit of the University of Exeter, can be regarded as one of the most important contributions dealing with lexicographic activities in Africa. The topics in this book are discussed with specific reference to the major geographic regions of Africa (i.e., Western Africa, Central Africa, Northern Africa, Eastern Africa, and Southern Africa). In the different chapters these regions are linked with a discussion of, respectively, the historical background (Kidda Awak, 1990), the user perspective (Busane, 1990), Arabic lexicography (El-Badry, 1990), the impact of computer technology (Mann, 1990b), and the information categories in dictionaries (Gouws, 1990). These chapters are preceded by a chapter presenting a linguistic map of Africa (Mann, 1990a) and followed by a chapter focusing on the organization of lexicography in Africa (Hartmann, 1990b). Albeit a relatively restricted study, the groundbreaking value of Hartmann (1990a) should not be underestimated.

The most comprehensive work on lexicography (i.e., the three-volume *Wörterbücher. Dictionaries. Dictionnaires: An international encyclopedia of lexicography*, Hausmann *et al.*, 1989–1991) also gives an account of lexicographic activities in Africa. A lengthy section entitled 'Lexicography of Individual Languages' has a subsection on 'The Languages of Black Africa,' which focuses briefly on three of the "four generally accepted African language phyla" (Bender, 1991: 2643), that is, the lexicography of Nilo-Saharan (Bender, 1991), the Niger-Kordofanian languages (Polomé, 1991), and the Khoisan languages (Hamp, 1991).The lexicography of the fourth of these phyla (the Afrasian languages) is not treated in this subsection, but the subsection on the lexicography of the Hamito-Semitic languages includes articles on Arabic lexicography (Haywood, 1991), lexicography of the Semitic languages of Ethiopia (Leslau, 1991), Berber lexicography (Bounfour, 1991), the lexicography of the Chadic languages (Newman and Newman, 1991), and the lexicography of the Cushitic languages (Gragg, 1991). Besides these contributions, Afrikaans lexicography is briefly discussed in an article on Dutch and Afrikaans lexicography (Heestermans, 1990), included in the subsection on the lexicography of the Germanic languages. Focusing primarily on language families and groups, the discussions are not really a realization of the section title ('Lexicography of Individual Languages'), but this publication does give a broad and general overview of some significant lexicographic projects on the African continent. A major contribution is the comprehensive selected bibliographies presented in each article. These bibliographies, with their listing of dictionaries and other literature, give a good indication of the nature and extent of the lexicographic practice of the respective languages and language groups. A supplementary fourth volume is currently being prepared and will include a substantial additional section on the lexicography of the languages of Africa.

Because of the dynamics of language and lexicographic activities and the ever-changing African scene, the factual component of publications like Hartmann (1990a) and Hausmann *et al.* (1989–1991) may currently perhaps not be as valid and correct as at the time of publication, but they remain authoritative reference sources, and any person interested in lexicographic activities on the African continent will be well advised to consult these books.

Moving Toward Dictionaries for Africa

Externally Motivated Lexicographic Endeavors

An overview of the lexicographic practice on the African continent and the dictionaries compiled

during the previous centuries emphasizes the profound influence of the colonial era and the extent of the lexicographic work performed by missionaries. Kidda Awak (1990: 9) maintains that the development of lexicography in Africa reflects three major events – the Christian missions, colonial expansion, and the development of modern linguistics and anthropology. According to Polomé (1991: 2647) the second half of the 19th century witnessed a great expansion of missionary work in sub-Saharan Africa. This resulted in many dictionaries compiled by the missionaries, displaying various degrees of sophistication and extent of coverage. The importance of the lexicographic work performed by missionaries should always be appreciated because of its pioneering nature. For many African languages, the missionaries and colonial administrators were responsible for the first dictionaries published in those languages (cf. Mavoungou, 2001; Mavoungou *et al.,* 2003; Mihindou, 2001). Although the dictionaries compiled by the missionaries and colonial administrators formed the basis for further lexicographic projects, these dictionaries were not really intended to benefit mother-tongue speakers of these African languages or to promote these languages. As Kidda Awak (1990: 10) states, they were not compiled for use by Africans but to assist the European explorers as expeditionary guides or to be used by missionaries in their attempts to learn the African languages for the purpose of evangelization. As instruments of linguistic and communicative empowerment, these dictionaries were not aimed at the speakers of the African languages but rather at European or non-African users. These lexicographic activities can be regarded as externally motivated, that is, although they were compiled and published in Africa, the motivation for their compilation was to assist users from outside Africa in their attempts to communicate with members of the local speech communities. Externally motivated dictionaries relied on a user profile not compatible with the user profile of the members of the speech community whose language constituted the subject matter of the dictionary. Externally motivated dictionaries may be planned and compiled in a multifunctional way to assist both mother-tongue and non-mother-tongue speakers of the treated language(s), but the typical missionary dictionary had a monofunctional character, being directed at the user who is not a mother-tongue speaker of the language of the local speech community treated in the dictionary.

Externally motivated dictionaries often are bilingual products, and in Africa these dictionaries often coordinated a local African language with a European language, typically the first language of the missionaries or the colonialization officials. The contributions in Hartmann (1990a) and Hausmann *et al.* (1989–1991) give evidence of such a situation of externally motivated bilingual dictionaries. These dictionaries were often not compiled to improve, document, or enhance the quality of the treated language but rather to strengthen the missionary or colonialization efforts.

Externally motivated dictionaries were also compiled in Africa for other reasons, and they were not only bilingual dictionaries. The external motivation sometimes did have a linguistic aim, albeit not the enhancement of the local non-European language. One such example comes from early Afrikaans lexicography. One of the first Afrikaans dictionaries was the *Proeve van Kaapsch taaleigen,* cf. Changuion (1844). Although this small dictionary had Afrikaans as a treated language, it was not compiled for the benefit of Afrikaans. The practical aim of Changuion was to rid Dutch spoken in South Africa from the 'corrupt' words and expressions that signaled the beginning of the new language, Afrikaans, which the lexicographer encountered in South Africa. This external motivation was a typical Eurocentered approach to African lexicography.

Some externally motivated dictionaries had also been compiled to benefit the local language of African speech communities. In 1884 the Dutch academic Mansvelt published an Afrikaans dictionary, *Proeve van een Kaapsch-Hollandsch idioticon met toelichtingen en opmerkingen betreffende land, volk en taal.* The macrostructure of this dictionary consisted of lemmata representing Afrikaans lexical items, and the primary treatment allocated to each lemma was a brief explanation of meaning presented in Dutch. The external motivation of this dictionary does not only stem from the fact that the lexicographer came from outside Africa but also that the target users of this dictionary, although the dictionary was published in South Africa, were not primarily members of the Afrikaans speech community but rather Dutch speakers in South Africa and in the Netherlands. Mansvelt compiled this dictionary to prove to these target users that Afrikaans differs sufficiently from the then-standard Dutch to be regarded as an emerging language and not merely as a dialect of Dutch. In this case, an externally motivated dictionary was compiled to benefit the local language.

Looking at different externally motivated dictionaries compiled in Africa during the early development of African lexicographic practice, major distinctions can be made with regard to the genuine purpose of these dictionaries and their lexicographic functions. The genuine purpose of a dictionary, cf. Wiegand (1998), implies that it is produced so that the target dictionary user in a typical context will have an

instrument to assist in reaching the goals that motivated the search. The genuine purpose of a dictionary is codetermined by, among others, its intended target user group. The genuine purpose of some of the externally motivated dictionaries had been directed at the needs of users, especially non-African users, whereas the genuine purpose of others had been directed at the subject matter of the dictionaries, that is, the language treated in the specific dictionary, aiming either to promote or to stigmatize this subject matter.

Internally Motivated Lexicographic Endeavors

One of the characteristic features of the linguistic situation of postcolonial Africa has been the reality of emerging indigenous languages. According to Mann (1990a: 5), the majority of countries in sub-Saharan Africa still have the language of the former colonial power as the language of administration and postelementary education. Although these colonial languages are still used and often remain the official language in many African countries, other countries have seen the indigenous languages coming to the fore to take their rightful position as language of general communication on a regional or national level, for instance, in Tanzania, where Swahili is the only official language. Even in some of the countries where the colonial language is the sole official language, recent decades have witnessed an increased interest in the local indigenous languages. This is the case in Gabon. After independence, French was declared to be the only official language. This was in line with the linguistic situation in the pre- independence era but differed from the rigid implementation of French as the official language during the colonialization era. Since independence the functional value of the indigenous languages has been acknowledged, and currently there is a strong movement toward the introduction of mother-tongue education at school and a much more lenient approach toward the multilingual reality.

Mann (1990a: 7) argued that the principal focus of lexicographic practice in Africa is the foreign learner, resulting in a situation where relatively few languages have monolingual dictionaries designed for the mother-tongue speaker. This is still a result of the colonial era and the work done by the missionaries. According to Polomé (1991: 2647), despite better linguistic training resulting in the production of lexical works of a higher quality, dictionaries compiled by missionaries are the only lexicographic products available in many African languages. This imbalance between monolingual and bilingual dictionaries can be seen quite clearly in the bibliographies of dictionaries given in Hartmann (1990a) and Hausmann *et al.* (1989–1991).

From a linguistic perspective, the ongoing dominance of colonial languages and the lack of dictionaries functioning as instruments for mother-tongue speakers may be regarded as slightly depressing. However, from a lexicographic perspective, given the situation in which colonial powers had such a tremendous influence for such a long time, a much more positive approach can be taken to the current situation. One of the most telling changes in African lexicographic practice is the switch from externally motivated to internally motivated projects due to an acknowledgment of the value of dictionaries as instruments in communication. Although a similar pattern is often still followed in the compilation of bilingual dictionaries (i.e., with the former colonial language and an indigenous African language selected as a language pair), as was followed in the dictionaries compiled by the missionaries, the current projects are internally motivated, whereas the missionary dictionaries were externally motivated. In practice it boils down to a different user profile, a different genuine purpose, different lexicographic functions, and a different selection of data to be included in the dictionaries. Important in this regard is that the switch from externally motivated to internally motivated dictionaries was initiated by a need to enhance the communicative performance of the members of the local speech communities. Whereas, for example, a French–Fang dictionary compiled by missionaries in Gabon had an external motivation, directed at the needs of the non-African missionary who wanted to communicate in Fang, a bilingual dictionary currently planned, treating the same language pair, has an internal motivation, directed at the needs of the Fang community in Gabon. In the preface of the Tanzanian *TUKI English–Swahili dictionary* (cf. Mlacha, 1996), it is stated that this dictionary was compiled to help the user comprehend English texts. Although this dictionary is not aimed at the local language but at an international language, the international language is coordinated with the official local national language to assist speakers of Swahili with the comprehension of English. The dictionary is directed at African users, illustrating an internally motivated project.

The switch from externally motivated to internally motivated dictionaries resulted in the present situation, where the majority of new lexicographic projects in Africa are characterized by an Afrocentered approach that deviates from the Eurocentered approach that prevailed, especially in the second half of the 19th and the first half of the 20th centuries.

A Stronger Theoretical Base

As indicated earlier, Polomé (1991: 2647) argued that better linguistic training has resulted in the production of lexical works of a higher quality. Better linguistic training did play a role, but a far greater role was played by a better understanding of lexicographic theory and a more aggressive application of this theory to lexicographic practice. Although metalexicography has not yet had a widespread influence on the African continent, it did make an impact on the work in a number of countries. In Africa, academic interest in theoretical lexicography reaches from as far north as Tunis to as far south as Stellenbosch (South Africa), with the Arab Lexicographic Association in Tunis and PROLEX, the Programme for Lexicography, in Stellenbosch. In this regard, university courses in lexicography play an important role in the training of theoretical and practical lexicographers as well as in creating an awareness of lexicography as a field of research and an independent discipline with its own job-creating possibilities.

The internally motivated principles identified with regard to the planning and compilation of dictionaries in Africa finds a parallel when it comes to theoretical training. A preference is often noted to undergo lexicographic training in Africa rather than elsewhere in the world. Gabon and its lexicographic interest can once again serve as a case in point. Traditionally many postgraduate students from Gabon further their studies, especially on doctoral level, abroad, for example in France or Belgium. The awakening of indigenous languages in Gabon and the realization of the need for the introduction of the heritage languages in the education system also resulted in an awareness of the need for dictionaries and trained lexicographers. Having heard of the practical training offered at the Bureau of the Woordeboek van die Afrikaanse Taal (the *Woordeboek van die Afrikaanse taal* being the comprehensive multivolume dictionary of Afrikaans) in Stellenbosch and the doctoral program in lexicography offered by the University of Stellenbosch, students from the Omar Bongo University in Libreville, Gabon, opted to enroll for their doctoral studies in lexicography at the University of Stellenbosch and to complement the theoretical work with practical training at the Bureau of the Woordeboek van die Afrikaanse Taal, instead of going to Europe. Their typical research focuses on theoretical models for various dictionaries needed in Gabon, and in this research the needs of the various Gabonese speech communities and their often unique situations of dictionary use play a decisive role. This once more illustrates a stronger Afro-centered approach instead of the traditional Euro-centered approach.

Lexicographic Associations, Institutes, and Publications

A striking feature of modern-day lexicography is the interactive relationship between theory and practice. On an international level, the establishment and activities of lexicographic associations have done a lot to encourage this development, cf. the role of leading associations like EURALEX in Europe and the DSNA in America. Hartmann (1990b: 73) argued that a regional or Pan-African lexicography society is urgently needed in Africa. Since Hartmann (1990a) lexicography has not only expanded in Africa but its development has also witnessed a much stronger relationship between the theoretical and practical components. In this regard, newly established lexicographic associations and other lexicographic institutes played a decisive role.

In 1995 AFRILEX, the African Association for Lexicography, was founded, and this association strives to promote all aspects of lexicography on the African continent. AFRILEX was founded in South Africa, and because the majority of its members are South Africans, many of its activities are in South Africa. However, the last few years have seen an increasing number of members from other African countries and from abroad joining AFRILEX. Since 1996 this association has hosted an annual international conference. The first seven conferences were in South Africa, but in 2003 the annual conference was held in Windhoek, Namibia, and in 2004 in Libreville, Gabon. By reaching out to other African countries, AFRILEX tries to realize its dream of becoming a truly pan-African association. Besides its annual conferences, AFRILEX has also hosted a number of regional seminars, specialized lexicographic workshops, and training sessions. Since 1991 the Bureau of the Woordeboek van die Afrikaanse Taal has published the annual journal *Lexikos,* and since 1996 *Lexikos,* still published by the Bureau of the Woordeboek van die Afrikaanse Taal, has been the official mouthpiece of AFRILEX. Over the last decade *Lexikos* has established itself as a leading international lexicography journal, and lexicographers from all over the world submit contributions to this journal. Africa now offers the rest of the world yet another platform for lexicographic publications. *Lexikos* has also done a lot to promote lexicographic discussion in Africa, and in each volume contributions from African scholars and lexicographers stimulate the ongoing development of lexicography in Africa.

At the University of Zimbabwe a new lexicographic journal, the *Journal of African Lexicography*, has recently been founded, illustrating the extent of

the internally motivated interest in lexicography on the African continent. The University of Zimbabwe has been one of the focal points in African lexicography. ALRI (the African Languages Research Institute) accommodates ALLEX (the African Languages Lexical Project). Within this project a variety of dictionaries of Zimbabwe's two main languages (Shona and Ndebele) have been compiled. The focus in ALLEX is on both general and terminological dictionaries.

At the University of Dar es Salaam the Institute of Kiswahili Research has been actively involved in lexicographic activities. Theoretical research has been complemented by practical lexicography, which resulted in the publication of the leading English-Swahili dictionary, the *TUKI English–Swahili dictionary.*

In North Africa the Arab Lexicographic Association in Tunis has played an active role in the development of Arabic lexicography, both on a practical and a theoretical level. One of the significant contributions of this association has been the International Symposium on Linguistic and Specialist Dictionaries, jointly organized with the University of Kuwait and hosted at this university in 2000. The proceedings of this symposium (Heliel *et al.,* 2000) can be regarded as an important point of departure for the further development of Arabic lexicography.

At the Omar Bongo University in Libreville, Gabon, GRELACO (the Research Group for Languages and Oral Cultures) has identified lexicography as one of its fields of specialization. According to its director, the policy of GRELACO is "to institute lexicography as a philosophy of work, of scientific co-operation and of a meeting platform for people who have the same will to advance man in his perpetual self-search through language, the most expensive attribute of man" (Emejulu, 2004). The lexicographic initiatives of GRELACO also resulted in the publication of a new book series, *Elements de lexicographie Gabonaise* (cf. Emejulu, 2001, 2002). These books do not only focus on Gabonese lexicography. Prominent international lexicographers also participate with Gabonese lexicographers to introduce a wide range of topics and to emphasize the active development of lexicography in Africa and its relation with general international metalexicographic trends.

The planning of lexicographic activities in Gabon has emphasized another aspect of lexicography that is becoming extremely relevant to the African continent – the financial aspect. In the *Gabonese Journal of the Language Sciences,* published by GRELACO, Emejulu (2000) argued that lexicography should be treated as an economic and commercial variable, governed essentially by market laws. It is a job-creating activity and should be deliberately oriented toward generating money. This illustrates an approach toward lexicography that had been unknown in the missionary and colonial era and emphasizes again the results of an internally motivated lexicographic momentum that has established itself in Africa. The commercial perspective on lexicography has already been introduced at an earlier stage when the Bureau of the WAT in Stellenbosch, South Africa, hosted a symposium in 1996 with the topic 'Lexicography as a financial asset in a multilingual South Africa.'

Focusing on lexicography as a financial asset raises the question of where a lexicographic process (cf. Wiegand, 1998) should be initiated and where the responsibility should reside for the planning and publication of dictionaries. The early African dictionaries, especially those published by missionaries and colonial administrators, were not planned as major commercial undertakings. Since then, however, publishers in Africa have gained quite adequately from the dictionary market, with a number of dictionaries being commercial successes. The language position in Africa does not allow viable commercial undertakings within the lexicography of every language or even every country, and to sustain the multilingual character of the majority of African countries governmental support is needed. In this regard, various models exist with the system of national lexicography units in South Africa as one of the most ambitious and innovative attempts.

Since 1994 South Africa has had eleven official languages. The Pan South African Language Board (PanSALB) was appointed by the South African government to implement and facilitate the policy of multilingualism. In the previous political dispensation South Africa had only two official languages, Afrikaans and English, with the nine indigenous Bantu languages functioning on a regional basis. The lexicographic development and the governmental support for dictionaries showed disparities. PanSALB embarked on a project to establish and fund a national lexicographic unit (NLU) for each of the official languages. This project has been completed, and currently these NLUs are working toward the compilation of a variety of dictionaries. Prior to the establishment of the NLUs, PanSALB hosted a number of seminars and training sessions to equip potential lexicographers with the necessary skills. These training sessions continued once the NLUs had been established, and PanSALB also employed experts in the field of lexicography to visit the NLUs on a regular basis for in-house training, focusing on both theoretical lexicography and the demands of the lexicographic practice, with reference to general issues as well as African-language-specific issues. To assist with the

ongoing training, a special publication will soon be available (cf. Gouws and Prinsloo, in press), in which aspects from the general theory of lexicography are applied to and illustrated with regard to the relevant African languages. This is an attempt to establish a closer link between theoretical lexicography and African lexicographic practice.

A very important aspect of the NLU project has been the emphasis on planning and management, and a number of training sessions were presented for the editors in chief as well as the members of the boards of directors of all the NLUs to equip them with the necessary managerial skills. The compilation of any dictionary is part of an overall lexicographic process, and the formulation of both a dictionary conceptualization plan and an organization plan constitutes an important phase in the lexicographic process. The organization plan covers all the administrative, logistic, and managerial aspects, but unfortunately lexicographic literature, research, conferences, and training very seldom pay attention to the crucial aspects of planning and managing lexicographic projects. In this regard, the South African initiatives are exemplary, helping not only with a sure footing for lexicography in Africa but also setting standards for lexicographic projects elsewhere in the world.

User Friendliness and a Dictionary Culture

According to Hausmann (1989: 13), user friendliness in lexicography implies that lexicography is adapted to society, whereas a dictionary culture implies society adapting to lexicography. A major challenge facing lexicographers and educationalists in Africa is to establish and maintain a dictionary culture. On a continent plagued by famine, drought, AIDS, and political instability, it is not always easy to convince politicians that a dictionary culture is a prerequisite for an environment of lifelong learning in which the community utilizes sources of reference to retrieve information successfully. Whereas lexicographers need to embark on lexicographic processes aimed at the compilation of user-friendly dictionaries, they should also join hands with educationalists to ensure that a dictionary culture can be established. In this regard, it is important that learners at the primary school level be targeted. Programs need to be developed so that learners can acquire dictionary use skills and become familiar with the spectrum of dictionary types available and the relevant data categories presented in these dictionaries, so as to satisfy their specific needs.

An advantage of internally motivated lexicographic projects is that the resulting dictionaries are compiled with specific target users, their needs, reference skills, and specific situations of usage in mind. In Africa there is neither a default user profile nor a default situation of dictionary use, and the lexicographer has to be cognizant of this situation when planning a dictionary. Lexicographers should, therefore, negotiate the physical environment of the user because these situations of usage can have a definite influence on the successful retrieval of information. Users of dictionaries in Africa may be in a position to consult the dictionary under either extremely favorable or extremely unfavorable circumstances. It may be consulted in a library, at home, or in an office within an environment supported by a well-established dictionary culture. Or it may be consulted by a user with no advantage of an existing dictionary culture. When planning a school dictionary, for instance, the African lexicographer has to realize that the dictionary might be used in a classroom with/without assistance of a teacher and/or at home with/without assistance of parents.

'Home' does not necessarily refer to a well-equipped study or working room. It may be under a tree or in a shanty house in a squatter camp without electricity. If a situation of usage is foreseen with little or no assistance from teachers or parents, the data presented in the dictionary and the way in which the data is presented should be adapted to assist the user in the best possible way. If the genuine purpose of the dictionary is to be achieved, the planning of the dictionary has to negotiate a wide spectrum of criteria.

In Conclusion

Lexicography in Africa has experienced lean times but is currently developing rapidly. This is due to the fact that the need for dictionaries compiled for the people of Africa motivates numerous lexicographic projects, and these dictionaries display a much stronger theoretical base. An interactive relation between theory and practice is stimulated by vibrant lexicographic associations, relevant publications, and a variety of training courses and opportunities directed at the real and often unique needs of lexicography in Africa.

African Linguistics: History

B Heine, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The first grammar of an African language appeared in 1659, when the Italian Capuchin Giacinto Brusciotto published a 98-page work on the Bantu language Kikongo (Kongo). As a distinct field, however, African linguistics developed only in the 19th century, when European missionaries studied African languages in some detail. By the end of that century there was a wealth of grammatical descriptions and dictionaries of African languages, some of which are still reference works today. Salient typological properties of African languages, such as complex tone structures and noun class systems, were identified and described in these works.

Comparative work also began in the 19th century; the first major genetic classification of African languages was published in 1854 by Sigismund Koelle. This classification served as a basis for later classifications by the Egyptologist Richard Lepsius in 1880 and, around the turn of the century, the German missionaries Carl Meinhof and Diedrich Westermann. The latter two became the leading figures of African linguistics, establishing African linguistics as an academic discipline. Meinhof and Westermann classified African languages into three major stocks: the 'Hamitic' languages of northern and northeastern Africa, the 'Sudanic' languages (*Sudansprachen*), spoken in a broad belt extending from Senegal in the west to Ethiopia in the east, and the Bantu languages of the southern half of Africa. This classification was based to quite some extent on 19th century language typology, in that the 'Hamitic' languages were said to belong to the inflectional type, whereas the Bantu languages were classified as agglutinating and the 'Sudanic' languages as isolating in structure.

Comparative African linguistics entered a new era when Joseph Greenberg (1963) proposed an alternative genetic classification. Pre-Greenbergian comparative African linguistics had suffered from the fact that no systematic distinction between different kinds of relationship was made, that is, it remained for the most part unclear whether the linguistic classifications proposed were intended to be genetically, typologically, or areally defined or, more commonly, were an amalgamation of all three kinds of relationship. According to Greenberg, the languages of Africa can be divided exhaustively into four families (or phyla): Niger-Kordofanian (including Niger-Congo), Afroasiatic, Nilo-Saharan, and Khoisan. Apart from minor revisions, this classification is now generally accepted, even if the evidence for the genetic unity of the last two families is not entirely satisfactory.

The question of areal relationship among African languages has been raised in a number of works, but so far no major results have emerged, apart from the fact that the Ethio-Eritrean highland region of northeastern Africa stands out as a linguistic area.

There is little information on the role of language in society in early studies of African linguistics. It is only since the 1960s, when the majority of African states attained their independence, that an interest in problems relating to multilingualism, language policy, etc. arose, resulting in a wide range of studies devoted to sociolinguistic problems of the African continent.

African Lexicography

R H Gouws, University of Stellenbosch, Stellenbosch, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article focuses on only a few aspects of the current state of affairs in lexicography on the African continent. The emphasis is not on a comprehensive account of all the lexicographic activities, but rather on a few topics portraying some significant changes and developments in African lexicography.

Scholarly Work Reflecting on Some Lexicographic Activities in Africa

Hartmann (1990a), a publication resulting from a workshop hosted at Exeter in March 1989 by the Dictionary Research Unit of the University of Exeter, can be regarded as one of the most important contributions dealing with lexicographic activities in Africa. The topics in this book are discussed with specific reference to the major geographic regions of Africa (i.e., Western Africa, Central Africa, Northern Africa, Eastern Africa, and Southern Africa). In the different chapters these regions are linked with a discussion of, respectively, the historical background (Kidda Awak, 1990), the user perspective (Busane, 1990), Arabic lexicography (El-Badry, 1990), the impact of computer technology (Mann, 1990b), and the information categories in dictionaries (Gouws, 1990). These chapters are preceded by a chapter presenting a linguistic map of Africa (Mann, 1990a) and followed by a chapter focusing on the organization of lexicography in Africa (Hartmann, 1990b). Albeit a relatively restricted study, the groundbreaking value of Hartmann (1990a) should not be underestimated.

The most comprehensive work on lexicography (i.e., the three-volume *Wörterbücher. Dictionaries. Dictionnaires: An international encyclopedia of lexicography*, Hausmann *et al.*, 1989–1991) also gives an account of lexicographic activities in Africa. A lengthy section entitled 'Lexicography of Individual Languages' has a subsection on 'The Languages of Black Africa,' which focuses briefly on three of the "four generally accepted African language phyla" (Bender, 1991: 2643), that is, the lexicography of Nilo-Saharan (Bender, 1991), the Niger-Kordofanian languages (Polomé, 1991), and the Khoisan languages (Hamp, 1991).The lexicography of the fourth of these phyla (the Afrasian languages) is not treated in this subsection, but the subsection on the lexicography of the Hamito-Semitic languages includes articles on Arabic lexicography (Haywood, 1991), lexicography of the Semitic languages of Ethiopia (Leslau, 1991), Berber lexicography (Bounfour, 1991), the lexicography of the Chadic languages (Newman and Newman, 1991), and the lexicography of the Cushitic languages (Gragg, 1991). Besides these contributions, Afrikaans lexicography is briefly discussed in an article on Dutch and Afrikaans lexicography (Heestermans, 1990), included in the subsection on the lexicography of the Germanic languages. Focusing primarily on language families and groups, the discussions are not really a realization of the section title ('Lexicography of Individual Languages'), but this publication does give a broad and general overview of some significant lexicographic projects on the African continent. A major contribution is the comprehensive selected bibliographies presented in each article. These bibliographies, with their listing of dictionaries and other literature, give a good indication of the nature and extent of the lexicographic practice of the respective languages and language groups. A supplementary fourth volume is currently being prepared and will include a substantial additional section on the lexicography of the languages of Africa.

Because of the dynamics of language and lexicographic activities and the ever-changing African scene, the factual component of publications like Hartmann (1990a) and Hausmann *et al.* (1989–1991) may currently perhaps not be as valid and correct as at the time of publication, but they remain authoritative reference sources, and any person interested in lexicographic activities on the African continent will be well advised to consult these books.

Moving Toward Dictionaries for Africa

Externally Motivated Lexicographic Endeavors

An overview of the lexicographic practice on the African continent and the dictionaries compiled

Afrikaans

T Biberauer, Newnham College, Cambridge, UK

Introduction

Afrikaans is the youngest fully standardized member of the West Germanic branch of the Indo-European language family. A daughter of Dutch (*Afrikaans* = the Dutch adjective meaning 'African'), it is primarily spoken in South Africa, where it is one of 11 official languages. Currently, it boasts the third largest speaker population, with only Zulu and Xhosa being more widely spoken (1996 Census). Afrikaans also represents a minority language in Namibia and, increasingly, in expatriate communities, notably in Britain, Australia, New Zealand, and Canada.

History

The precise circumstances surrounding the development of Afrikaans as a language in its own right have been energetically disputed. What is uncontroversial is that the Dutch East India Company's establishment of a refreshment station in 1652 led to the introduction of various varieties of 17th-century Dutch at the Cape. During the next 150 years, these Dutch speakers came into contact with indigenous Khoekhoe, with slaves imported from Asia (India, Indonesia, Sri Lanka), East Africa, and Madagascar, and also, more sporadically, with French- and German-speaking Europeans. Written records reveal that a distinctive local variety of Dutch – so-called Kaaps Hollands (Cape Dutch), which was also variously described at the time as geradbraakte/gebroke/onbeskaafde Hollands ('mutilated/broken/uncivilized Hollandic'), verkeerde Nederlands ('incorrect Dutch') and kombuistaal ('kitchen language') – already existed by the mid-18th century. There are three main positions on how this extraterritorial variety became a distinct, structurally simplified and reorganized language: the superstratist, variationist/interlectalist, and creolist positions. On the superstratist view, Afrikaans is essentially the product of the normal linguistic evolution that typically occurs in the absence of strong normative pressures, with the influence of Khoekhoe and the slave languages (i.e., Malay and Creole Portuguese) being confined to the lexical domain (see below). The variationist/interlectalist position similarly downplays the role of the non-Germanic languages interfacing with Dutch at the Cape, identifying dialect-leveling/convergence as the impetus behind the emergence of a new Dutch-based language. By contrast, the creolist view analyses Afrikaans as a semicreole, the product of interaction between the 'creolizing' and 'decreolizing' influences of the matrilectal Cape Dutch(es) and the Dutch-based pidgin(s) spoken respectively by the Cape's European and non-European populations. Exactly when Afrikaans was 'born' is also disputed, but official recognition of its distinctness came in 1925 when it was finally standardized following two Taalbewegings ('language movements') and recognized, alongside English, as one of South Africa's two official languages. The Bible was translated into Afrikaans in 1933 and a rich literary and cultural heritage accrued during the 20th century, with two major annual arts festivals now being dedicated solely to Afrikaans (the Klein Karoo Kunstefees/'Little Karoo Arts Festival' and Aardklop/'Earth-beat'). Because of its unfortunate association with the apartheid policy pursued between 1948 and 1994, there are, however, concerns about Afrikaans's future in post-apartheid South Africa and there has, in recent years, been a move to promote it as the only South African language which is both European *and* African.

Varieties of Afrikaans

The three basic varieties of Afrikaans traditionally identified are Kaapse Afrikaans (Cape Afrikaans) spoken in the western Cape, Oranjerivier–Afrikaans (Orange River Afrikaans) spoken in the northwestern Cape, and Oosgrens–Afrikaans (Eastern Cape Afrikaans), the variety that provided the basis for standard Afrikaans, spoken in the rest of the country (see Figure 1). Kaapse and Oranjerivier Afrikaans are both spoken by people of color, the former reflecting particularly strong Malay and English influences, and the latter, that of Khoekhoe. Various subvarieties are discernible within these regional boundaries, one example being the Arabic-influenced Afrikaans spoken by Cape Muslims. Additionally, Afrikaans also forms the basis of a number of special group languages. Of these, Bantu-influenced Flaaitaal ('Fly-language'), a township argot spoken mostly by black migratory workers in urban areas, represents the best-studied case. During the apartheid era, normative pressures promoting suiwer Afrikaans ('pure Afrikaans') were strong and often directed against Anglicisms. Sociopolitical changes and attempts to promote Afrikaans as more 'inclusive' have, however, led to a more relaxed attitude in many contexts, with many younger speakers frequently speaking and writing Afrikaans, which is lexically heavily influenced by South Africa's other languages, particularly English. In its turn, Afrikaans has also left its mark on the other languages spoken in South Africa, with South African English featuring lexical items such as *braai* ('barbecue'), *veld*

Figure 1 Map of South Africa showing the nine provinces created in 1994 and the areas in which the three main regional varieties of Afrikaans are spoken. Key: dark grey, Cape Afrikaans; light grey, Orange River Afrikaans; mid grey, Eastern Frontier Afrikaans.

('bush'), and *stoep* ('verandah'); Xhosa with *ispeki* (> *spek* = 'bacon'), *isitulu* (> *stoel* = 'chair'), and *ibhulukhwe* (> *broek* = 'trousers'); and Sotho, with *potloto* (> *potlood* = 'pencil'), *kerese* (> *kers* = 'candle'), and *sekotelopulugu* (> *skottelploeg* = 'disc-plough').

Formal Features

Many aspects of Afrikaans's formal structure represent simplifications of their Dutch counterparts, but the language also features a number of structural innovations. Phonologically, striking differences between Afrikaans and Dutch are that Afrikaans features:

- apocope of /t/ after voiceless consonants – cf. Afrikaans *lig* ('light') and *nag* ('night') versus Dutch *licht* and *nacht*
- syncope of intervocalic /d/ and /g/ – cf. Afrikaans *skouer* ('shoulder') and *spieël* ('mirror') versus Dutch *schouder* and *spiegel*
- fricative devoicing – cf. Afrikaans *suid* ('south') versus Dutch *zuid*
- diphthongization of long vowels – cf. Afrikaans [bruət] versus Dutch [bro:t] for *brood* ('bread').

There are also consistent orthographic differences, with Dutch *ij* and *sch* being rendered in Afrikaans as *y* and *sk*, respectively.

Morphologically, Afrikaans is characterized by extreme deflection: it lacks both Dutch's gender system and its system of verbal inflection, pronouns being the only nominals exhibiting distinct forms, although fewer than in Dutch (cf. Afrikaans *ons,* which corresponds to both Dutch *wij* – 'we' and *ons* – 'us'), and all lexical verbs taking the same form, regardless of their person, number, and finiteness specifications. Afrikaans also differs from Dutch in employing reduplication – cf. *gou-gou* ('quick-quick'), *stuk-stuk* ('piece-piece,' i.e., bit by bit), and *lag-lag* ('laugh-laugh,' i.e., easily).

Afrikaans's retention of West Germanic's distinctive word-order asymmetry (main clauses being verb–second/V2 and embedded clauses, verb–final) distinguishes it from Dutch-based creoles, which are exceptionlessly SVO and undermines extreme creolist accounts of its origins. Among the syntactic peculiarities that distinguish Afrikaans from Dutch are:

- its negative concord system – cf. Afrikaans *Ons lees nie hierdie boeke nie* ('Us read not here – the books NEGATIVE') and Dutch *Wij lezen niet deze boeken* ('We read not these books')
- verbal hendiadys – cf. Afrikaans *Ek sit en skryf* ('I sit and write') versus Dutch *Ik zit te schrijven* ('I sit to write,' i.e., I sit writing)

- use of *vir* with personal objects – cf. *Ek sien vir jou* ('I see for you') versus Dutch *Ik zien je* ('I see you')
- *dat*-dropping in subordinate clauses – cf. *Hy weet ek is moeg* ('He knows I am tired'), which alternates with *Hy weet dat ek moeg is* ('He knows that I tired am'), whereas standard Dutch permits only the latter
- retention of main-clause ordering in subordinate interrogatives – cf. *Hy wonder wat lees ek* ('He wonders what read I') versus *Hy wonder wat ek lees* ('He wonders what I read'), which is the only permissible structure in Dutch.

Lexically, Afrikaans differs substantially from Dutch in featuring borrowings from Khoekhoe, Malay, and Creole Portuguese (see 'Lexical Borrowing' section), and also, as a consequence of the 'suiwer Afrikaans' policy, in respect of many neologisms, which were created to avoid adopting an English expression – cf. *skemerkelkie*, *rekenaar,* and *trefferboek* or *blitsverkoper* whereas Dutch uses *cocktail*, *computer,* and *bestseller,* respectively.

The Taalmonument

Afrikaans is unique in being the only language with its own monument (see Figure 2). The *Taalmonument* ('language-monument') in Paarl was erected to celebrate the 100-year anniversary of the 1875 *Eerste Taalbeweging* ('First Language-movement') at which the first concerted calls for the elevation of Afrikaans to the status of written language were made. The monument was inspired by the writings of two prominent Afrikaans writers, C. J. Langenhoven (1873–1832) and N. P. van Wyk Louw (1906–1970). Langenhoven visualized the growth potential of Afrikaans as a hyperbolic curve, whereas van Wyk Louw conceived of Afrikaans as "the language that links Western Europe and Africa … form[ing] a bridge between the enlightened west and magical Africa" (1961, 'Laat ons nie roem'/'Let us not extoll' in *Vernuwing in die Prosa/Renewal in prose*. Cape Town: Human and Rousseau). The monument symbolizes these ideas as follows:

- it features two curves (A and B) representing the influences of Europe and Africa respectively
- A, which starts as a colonnade, flows into the main column symbolizing Afrikaans (D), signifying the direct manner in which Afrikaans grew out of Dutch
- B, which features three semispherical mounds symbolizing the indigenous languages and cultures of

- column E represents the Republic of South Africa, the political entity established in 1961, within which Afrikaans was well established as one of two official languages.

Afrikaans was Written in Arabic

By the mid-19th century, Afrikaans was being used by the Cape Muslim community in the exercise of their religion and some of the *imams* were beginning to translate holy texts into Afrikaans using Arabic script. The first of these **ajami** (Arabic–Afrikaans) manuscripts, the *Hidāyat al-Islām* ('Instruction in Islam'), is said to have been prepared in 1845 but is no longer extant. The first ajami text to be published, the *Bayānu ddīn* ('Exposition of the religion'), was written by Abu Bakr in 1869 and published in Constantinople in 1877. Seventy-four texts, written between 1856 and 1957, survive today.

Lexical Borrowings

Afrikaans has drawn on the lexical resources of a wide variety of languages with which it has been in contact during the course of its history. Here are some examples of the range and nature of this borrowing:

- From Khoekhoe: animal names such as *geitjie* ('lizard'), *kwagga* (a zebra-like creature), and *gogga* ('insect'); plant names like *dagga* ('cannabis'); place names such as *Karoo* and *Knysna*; and also miscellaneous items such as *kierie* ('walking-stick'), *abba* ('carry') and *kamma* ('quasi/make-believe')
- From Malay: *baie* ('very/much'), *baadjie* ('jacket'), *baklei* ('fight'), *piesing* ('banana'), *rottang* ('cane'), *blatjang* ('chutney')
- From languages spoken on the Indian subcontinent: *koejawel* ('guava'), *katel* ('bed')
- From Creole Portuguese: *mielie* ('corn/maize'), *kraal* ('pen/corral'), *tronk* ('jail')
- From Bantu languages spoken in South Africa: *malie* ('money'), *aikôna* ('no'), *hokaai* ('stop'), *babelas* ('hangover').

Afroasiatic Languages

J Crass, Johannes Gutenberg Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The Afroasiatic languages are spoken by more than 250 million people living in northern Africa, the Horn of Africa, and in South West Asia. The Afroasiatic language phylum (or superfamily) contains more than 200 languages, even 372 according to Grimes (2000). In addition, a number of languages are documented only literally. With the exception of the extinct Sumerian, Afroasiatic has the longest documented history of any language phyla in the world: Egyptian was recorded as early as 3200 B.C., while the documentation of Semitic languages goes back to 2500 B.C. The name Afroasiatic was established by Greenberg (1952), replacing the inappropriate term Hamito-Semitic (or rarely Semito-Hamitic) that is still used by a few scholars. Other terms with little acceptance are Afrasian, Erythraic, and Lisramic.

Classification and Geographical Origin

The Afroasiatic languages are divided into six branches, namely Berber, Chadic, Cushitic, Egyptian, Omotic, and Semitic. Whereas Egyptian (Arabic, Egyptian Spoken) is a single language with four stages (Old-, Middle-, and New-Egyptian and Coptic), the other five branches are families. Chadic encompasses the largest number of languages – namely 195 according to Grimes (2000) or approximately 140 according to Newman (1992) – followed by Semitic (74), Cushitic (47), Omotic (28), and Berber (26), the latter four numbers as stated by Grimes (2000). These six branches are considered 'sister families,' i.e., they are equal, flat, and parallel. However, there are attempts to connect these branches to larger units. Semitic and Berber are relatively closely related, and both are somehow connected to Cushitic (Zaborski, 1997). Bender (1997) calls this group of branches macro-Cushitic and speculates on its connection with Indo-European.

According to Diakonoff (1988) and Bender (1997), the original homeland of the speakers of Afroasiatic languages was in the southeast of today's Saharan desert, while Militariev and Shnirelman (1984) believe it was in Asia. The former scenario seems likely because – except for Semitic – all families of the Afroasiatic phylum are spoken exclusively in Africa. The latter scenario is also possible, however, because parts of the lexis are shared by the Afroasiatic languages, the Sumerian language, and the Caucasian languages (Hayward, 2000: 95).

History of the Investigation of Afroasiatic Languages

In the Middle Ages, the genetic relationship between the Semitic languages Arabic (Standard Arabic) and Hebrew was discovered only after the study of Afroasiatic languages had already begun. Likewise, only after Egyptian was deciphered in the 19th century did the affinity of Egyptian to Semitic became apparent. A short time later, Berber and Cushitic were recognized as belonging to this phylum. The Chadic languages as a whole were classified as Afroasiatic

Introduction

The Afroasiatic languages are spoken by more than 250 million people living in northern Africa, the Horn of Africa, and in South West Asia. The Afroasiatic language phylum (or superfamily) contains more than 200 languages, even 372 according to Grimes (2000). In addition, a number of languages are documented only literally. With the exception of the extinct Sumerian, Afroasiatic has the longest documented history of any language phyla in the world: Egyptian was recorded as early as 3200 B.C., while the documentation of Semitic languages goes back to 2500 B.C. The name Afroasiatic was established by Greenberg (1952), replacing the inappropriate term Hamito-Semitic (or rarely Semito-Hamitic) that is still used by a few scholars. Other terms with little acceptance are Afrasian, Erythraic, and Lisramic.

Classification and Geographical Origin

The Afroasiatic languages are divided into six branches, namely Berber, Chadic, Cushitic, Egyptian, Omotic, and Semitic. Whereas Egyptian (Arabic, Egyptian Spoken) is a single language with four stages (Old-, Middle-, and New-Egyptian and Coptic), the other five branches are families. Chadic encompasses the largest number of languages – namely 195 according to Grimes (2000) or approximately 140 according to Newman (1992) – followed by Semitic (74), Cushitic (47), Omotic (28), and Berber (26), the latter four numbers as stated by Grimes (2000). These six branches are considered 'sister families,' i.e., they are equal, flat, and parallel. However, there are attempts to connect these branches to larger units. Semitic and Berber are relatively closely related, and both are somehow connected to Cushitic (Zaborski, 1997). Bender (1997) calls this group of branches macro-Cushitic and speculates on its connection with Indo-European.

According to Diakonoff (1988) and Bender (1997), the original homeland of the speakers of Afroasiatic languages was in the southeast of today's Saharan desert, while Militariev and Shnirelman (1984) believe it was in Asia. The former scenario seems likely because – except for Semitic – all families of the Afroasiatic phylum are spoken exclusively in Africa. The latter scenario is also possible, however, because parts of the lexis are shared by the Afroasiatic languages, the Sumerian language, and the Caucasian languages (Hayward, 2000: 95).

History of the Investigation of Afroasiatic Languages

In the Middle Ages, the genetic relationship between the Semitic languages Arabic (Standard Arabic) and Hebrew was discovered only after the study of Afroasiatic languages had already begun. Likewise, only after Egyptian was deciphered in the 19th century did the affinity of Egyptian to Semitic became apparent. A short time later, Berber and Cushitic were recognized as belonging to this phylum. The Chadic languages as a whole were classified as Afroasiatic

languages by Greenberg in the 1950s. The sixth branch, Omotic, was regarded as a branch of Cushitic until the end of the 1960s, and while some scholars still consider this to be true (Lamberti, 1991; Zaborski, 1986, 1997), most believe that Omotic is an independent branch of Afroasiatic (Fleming, 1969). A few scholars even regard it as the first family that split off from Proto-Afroasiatic, the reconstructed ancestor of all Afroasiatic languages (Fleming, 1983; Ehret, 1995).

Finally, it should be mentioned that Hetzron (1980) sees Beja (Bedawi) – generally regarded as the only representative of North Cushitic – as another family of Afroasiatic, but Zaborski (1984) does not agree with this view.

For a long time, the structure and features of Semitic determined which languages belonged to the Afroasiatic language phylum. Most likely this was because Arabic and Hebrew were the first languages European scholars knew. Also, for a significant period of time, racial, even racist prejudices dominated classification suggestions of the Afroasiatic languages. In the mid–19th century, the idea of a language family, of which Semitic is one branch, was born. The term Hamitic, derived from the name Ham, the second son of Noah, was created in opposition to Sem, the name of the first son of Noah, who was the eponym of the Semitic languages. All Afroasiatic languages related to Semitic, but considered to be non-Semitic, were classified as Hamitic, the second branch of 'Hamito-Semitic.' These criteria were a mixture of linguistic (genetic and typological), physical anthropological, and partly geographical features.

Lepsius (1863), the first important exponent of this theory, classified the Hamitic branch into four groups, namely (1) Egyptian; (2) Ethiopic (Ge'ez), i.e., mostly Cushitic languages spoken in the Horn of Africa; (3) Libyan, i.e., Berber and the Chadic language Hausa; and (4) Hottentottan (Nama), i.e., languages of the Khoisan phylum of southern and southwestern Africa. In 1880 he included even Maasai – a language of the Nilosaharan phylum – in the Hamitic branch. Lepsius's main criterion for his classification was grammatical gender. African languages possessing the masculine vs. feminine gender distinction were classified Hamitic, while African languages without gender distinction were called 'Negersprachen,' i.e., 'languages of the negros.'

The most famous exponent of the Hamitic theory was Meinhof (1912), who tried to work out the features of the Hamitic languages by considering genetic, typological, and physical anthropological features. Meinhof was of the opinion that one must distinguish more 'primitive' from more 'highly developed' languages, a criterion that he believed correlated with the mental abilities of the speakers of the respective languages. In the tradition of Schleicher, he believed that inflecting languages reflect the highest level of linguistic evolution. This typological feature of the Hamitic languages derived from a race called 'Hamites' who had white skin, curled hair, and other physical anthropological features considered prototypical of the old Egyptian and Ethiopide types.

Besides grammatical gender, ablaut and other typological features of the Indo-European and Semitic languages were the main linguistic criteria Meinhof took into consideration. He classified as Hamitic not only Afroasiatic languages (except Semitic) but also languages like Ful (Fulfulde, Adamawa) (an Atlantic language of the Niger Congo phylum), Maasai, and other Nilotic languages of the Nilosaharan phylum and languages of the Khoisan phylum, earlier excluded by others from the Afroasiatic languages.

The first opponents of the Hamitic theory were Beke (1845) and Lottner (1860–61), later followed by Erman (1911) and Cohen (1933) who considered – as did the aforementioned scholars – the branches of this phylum to be 'sister families.' According to Sasse (1981: 135), the final breakthrough of this theory and the beginning of a new era in the study of Afroasiatic languages was marked by Cohen (1947). Greenberg (1952, 1955) finally provided evidence that a number of languages had to be excluded from the Afroasiatic language phylum, and he created the Chadic family by unifying the former 'chadohamitic' language Hausa with the rest of the Chadic languages that until then had been classified as non-Afroasiatic languages.

Shared Features

The genetic relationship among the six branches of Afroasiatic is shown best by some shared morphological features (cf. Hayward, 2000: 86ff; Sasse, 1981: 138ff). These are case marking, plural formation on nouns, gender marking, pronouns, verb inflection, and verb derivation.

The basic nominal form of Proto-Afroasiatic, functioning as the direct object of a verb, is termed 'absolutive,' marked by the suffix *-*a*. In Cushitic and – as Sasse (1984) claims – in Semitic and Berber, its function is more widespread, so it can be treated as the functionally unmarked form. The nominative, marked by *-*u*, is used for subject NPs. A similar morphology can be assumed for Egyptian and Omotic, the latter having a reconstructed accusative marking system (Hayward and Tsuge, 1998), i.e., the unmarked form is the nominative and not – as reconstructed for Semitic, Berber, and Cushitic – the absolutive. Chadic, however, is not concerned here since it generally lacks case marking. Modern languages with a marked

nominative case system occur mainly in central and southwestern Ethiopia and adjacent areas where this system of case marking is an areal feature found not only in several Cushitic and Omotic languages, but also in languages of the Nilosaharan phylum.

Complex plural formation of nouns is another characteristic of many Afroasiatic languages. A likely pattern of Afroasiatic plural formation is the "ablaut to *a*, usually in the last stem syllable of a noun ... [partly] accompanied by reduplication, and sometimes trigger[ing] dissimilation or assimilation of other stem vowels of the plural" (Hayward, 2000: 92; cf. Greenberg, 1955). Other reconstructed plural markers are a suffix containing a labial-velar glide and a suffix *-t*, the latter not easy to disentangle from the *-t* of the feminine gender marker. Such a gender marker is found, in all six branches of Afroasiatic. In addition gemination of consonants marking nominal and verbal plurality is widespread.

Two formally distinct sets of pronouns must be set up for Afroasiatic, the first for the absolutive, the second for the nominative case. Due to the shift of a marked nominative to a marked accusative system, the absolutive pronouns often were converted to nominative pronouns, e.g., in Berber and Chadic, so consequently, the subject pronouns of these languages just happen to look like object pronouns of other languages. Gender markers **n-* and **k-* for masculine and **t-* for feminine are often derived from demonstrative elements. These gender markers may be combined with the pronominal gender marker **-uu* for masculine and **-ii* for feminine and function as demonstrative pronouns, especially of the near deixis. This applies exactly to the Highland East Cushitic language K'abeena, in which the demonstrative pronouns have an additional morpheme *n* – probably a definite marker – that results in the forms *kuun* and *tiin*.

Subject agreement on the verb may be marked in two ways, either by a so-called prefix conjugation or by a suffix (or stative) conjugation. Some languages make use of both, e.g., most modern Semitic languages; others have only the suffix conjugation, e.g., Egyptian and many Cushitic languages. The reconstructed subject-agreement morphemes of the prefix conjugation are **'-* (1S), **t-* (2S, 3Sf, 2P), **y-* (3Sm), and **n-* (1P). Suffixes differentiate number and partly gender.

Some morphemes used for verb derivation are found in many Afroasiatic languages, so most probably those are a feature of Proto-Afroasiatic. The transitivizing/causativizing **s-* ~ **-s* and the intransitivizing/passivizing **m-* ~ **-m*, **n-*, and **t-* ~ **-t* belong to these morphemes.

Furthermore, hundreds of lexical items have been reconstructed for Proto-Afroasiatic by Ehret (1995) and Orel and Stolbova (1995) of which a small number "seem unlikely to be disputed" (Hayward, 2000: 94), e.g., **dim-/*dam-* 'blood', **tuf-* 'to spit', **sum-/*sim-* 'name', **sin-/*san-* 'nose', **man-/*min-* 'house', and **nam-/*nim-* 'man'.

The rich consonant inventory of Proto-Afroasiatic – Orel and Stolbova 1995: xvi reconstruct 32, Ehret 1995: 72, even 42 consonants – includes three obstruents, namely, a voiceless, a voiced, and a glottalized sound "not only for most places of articulation but also for certain other articulatory parameters, for example, among lateral obstruents, sibilants and labialised velars" (Hayward, 2000: 94). Furthermore, two pharyngeals, two glottals, and four uvulars are reconstructed by Orel and Stolbova (1995).

Typologically, there is a contrast between Berber, Egyptian, and Semitic on the one hand and Chadic, Cushitic, and Omotic on the other. According to Bennett (1998: 22), the first three languages "generally have (or can be reconstructed as having had) three underlying vowels, no tonal contrasts ... and typically triconsonantal roots that at least in the verbal system seem not to include vowels." He writes that the latter three, however, are characterized by "relatively full vowel systems, tonal contrasts, and roots of varied length that normally include a vowel" (Bennett, 1998: 22). Concerning word order, Afroasiatic languages can be divided as follows: Berber, Chadic, and Semitic languages outside Ethiopia have VO word order, while Cushitic, Omotic, and Ethiosemitic languages generally have OV word order.

Finally, two hypotheses must be mentioned. Diakonoff (1965) is of the opinion that Proto-Afroasiatic was an ergative language, a hypothesis adopted by Bender (1997) and for Semitic by Waltisberg (2002). The second hypothesis concerns the possible substrate influence of Afroasiatic languages on the Celtic languages (cf. Adams, 1975; Gensler, in press).

Age: Apparent Time and Real Time

G Sankoff, University of Pennsylvania, Philadelphia, PA, USA

During the 1960s linguists working in the structuralist tradition and in the evolving generative paradigm tended to treat the individual speaker of a language as the natural locus of linguistic inquiry. The field had inherited the traditional Saussurean dichotomies separating language from speech and synchronic from diachronic linguistics. The grammar of the individual, conceptualized as an abstract, internalized, mental construct, was construed as having a systematic character. Speech communities, if considered at all, were characterized as epiphenomena – nothing more than the sum of individual idiolects.

The first research to show how synchronic evidence can be used to reconstruct the history of language change also pointed the way to understanding the systematic character of the speech community. In 1961 Labov carried out sociolinguistic interviews with 69 residents of Martha's Vineyard for his study of the (ay) and (aw) diphthongs (1963). He calculated an index value for the height of the vowel nucleus for each speaker for each diphthong, discovering that the nuclei of both diphthongs were progressively higher with each younger age cohort (although those under 30 reversed the trend, an effect explained by other criteria). There were two possible explanations for the general age-related pattern. The older speakers might have started out life with the high index values (more centralized diphthongs) typical of the younger speakers of 1961, then progressively lowered their nuclei decade by decade, as they grew older. Labov referred to this interpretation as 'age grading.' On the other hand, perhaps the pattern was attributable to the oldest speakers having learned the language at a time when the community as a whole had lower values, and their speech reflected the state of the language at that earlier date. Under this interpretation, the regular increase across the four age cohorts would represent a generational change in progress. Labov referred to this as the 'apparent time' interpretation. How did he decide which interpretation was the most plausible?

The most important piece of evidence came from earlier records. In 1933 the four informants interviewed for the Linguistic Atlas of New England (LANE) were between 56 and 82 years old. They showed "only moderate centralization of (ay)" and a rating for (aw) that was "for all practical purposes, zero" (Labov, 1972). In comparing the older speakers of thirty years earlier to the older speakers in the 1961 interviews, Labov felt confident that the apparent time interpretation was correct. However, he noted as a caveat in this first study of apparent time that "the effect of age [grading] . . . may indeed be a secondary factor in this distribution" (1972).

The Martha's Vineyard study was a prelude to Labov's New York City study (1966) that served as the primary example of how synchronic and diachronic linguistics could be reintegrated (Weinreich *et al.*, 1968). There followed an avalanche of convergent research by sociolinguists, dialectologists, historical linguists, and, recently, corpus analysts in the ensuing four decades. Although space does not permit a survey of the hundreds of studies involved (a more complete listing of research through 2001 can be found in Sankoff, 2005), this review will be concerned mainly with what recent research has revealed about the relationship between apparent and real time.

Most of the studies that have examined gradient age distributions for potential evidence of change in progress have seriously entertained both of the alternative interpretations originally proposed by Labov. Most researchers have tried to find, and many have succeeded in finding earlier evidence that might provide a point of comparison with the modern data. In addition to his own use of the LANE data, Labov (1965) cited Hermann's use of Gauchat's 1905 observations on the dialect of Charmey, Switzerland, and sources dating back to 1896 on New York City. In their study of the change from alveolar to velar/uvular /r/ in Montreal French, based on data collected in 1971, Clermont and Cedergren (1981) were able to refer to a survey from the late 1940s that showed clearly that alveolar [r] was then the dominant variant. This corroborated the apparent time interpretation of the 1971 data, which patterned according to the classic S curve typical of changes in progress, as depicted in Figure 1. If the majority of studies attempted to carefully weigh both interpretive options, it must also be noted that most eventually came down on the side of apparent time. Two studies whose results were interpreted as age grading were Guy and Boyd's investigation of (t,d) deletion in final consonant clusters (1990), and Macaulay's study of glottal stop alternating with [t] in Glasgow (1977).

Guy and Boyd found that although rates of (t,d) deletion were stable across the age spectrum for both monomorphemic words (like *mist, raft*) and past tense (*missed, laughed*), another grammatical category showed a regular progression: the final clusters in semi-weak verbs (*kept, swept, told*). Their

Figure 1 Mean percentage use of the innovative velar [R] by 119 Montreal French speakers in 1971, grouped by decade of birth (adapted from Clermont and Cedergren, 1979).

Figure 2 Percentage of glottal stop variants of /t/ used by female speakers in Glasgow (adapted from Macaulay, 1977).

interpretation was that although younger speakers analyzed the vowel alternation in the stem as the indicator of past tense, treating final clusters in semi-weak verbs like those in monomorphemic words, older speakers had reanalyzed final (t,d) in these clusters as carrying past tense information.

In the case of glottal stops, both Chambers (1995) and Sankoff (2005) proposed the age grading interpretation to account for the differences Macaulay found among 10 year olds, 15 year olds, and adults. Results for female speakers are shown in Figure 2. Speakers were drawn from four occupational groups (ordered such that 1 is the highest status group), and the adults selected were parents of the children. Whereas the younger children of groups 2a and 2b showed the high level of use of glottals typical of both adults and children in the two lowest status groups, the adolescents in the two highest status groups (1 and 2a) diverged toward the adult norms for their groups, with much lower levels of use of glottals. Noting that his interpretation is an inference about how this synchronic data can be understood in terms of life stages, Chambers commented, "Although the norm-enforcement mechanisms cannot prevent the class-insensitive youngsters from learning to use the glottal stop variant, they can prevent its perpetuation into adolescence" (Chambers, 1995).

In these two studies in which age grading seemed the most likely interpretation of synchronic data, it was easiest to see how age grading might fit into the picture when the variable was stable. We know historically that English final consonant cluster simplification has been stable for some time, and Guy and Boyd's results also showed no age effect for the two major word classes – only in the minority 'semi-weak' verbal category did the effect appear. In the case of glottal stop, the age grading interpretation was somewhat more adventurous, and we will follow that adventure in the light of a new study below.

Looking at age grading and apparent time as alternative interpretations of data gathered at one point in time, Labov's summary of the various possibilities is presented in Table 1. If the age distribution is flat, either no change is happening (Interpretation 1), or the whole community, young and old, are changing at the same rate and therefore show no age differences (Interpretation 4). Interpretations 2 and 3 are those that interest us more particularly. The same pattern depicted, for example, in Figure 1, where the likelihood of using velar [R] is related to a speaker's decade of birth, may mean that all these speakers have been

Table 1 Patterns of change in the individual and the community[a]

Synchronic Pattern	*Interpretation*	*Individual*	*Community*
Flat	1 Stability	Stable	Stable
Regular increase/decrease with age	2 Age grading	Unstable	Stable
Regular increase/decrease with age	3 Generational change (apparent time)	Stable	Unstable
Flat	4 Communal change	Unstable	Unstable

[a]Adapted from Labov, 1994.

unstable, decreasing their use of [R] as they aged. The community overall would be stable; the language would not be changing; and the correct inference would be Interpretation 2: age grading. This same S curve, however, might produce the inference that the community was unstable – a change was going on in the language, but individual speakers, once they had acquired language as children, were stable across their life spans. This is Interpretation 3: apparent time.

As long as we consider clear-cut cases – change or no change – it seems that age grading is a strong alternative interpretation for gradient age distributions where no change is occurring. But what if we look at age not in the demographic sense (as a gradient variable having to do with year of birth), but rather in terms of the lifespan of people for whom different periods may involve very different sociolinguistic relationships? In addition to the important fact that children have greater plasticity in their capacity for language learning (Lenneberg, 1967; Sankoff, 2004), sociolinguists have pointed to the fact that, for example, different periods of people's lives involve them differentially in their relationship to the standard language (Eckert, 1997) and possibly also in their contacts with the opposite sex (Cameron, 2000).

Two earlier observations now become relevant. First, Labov's caveat that perhaps both apparent time and age grading were relevant to correctly interpreting the Martha's Vineyard data has been proven to be true in many subsequent real-time studies. This was abundantly clear by 1994, when Labov reviewed several such studies, finding a combination of age grading and real language change in longitudinal work by Trudgill in a restudy of Norwich (1988), in Cedergren's (1987) restudy of Panama City, and in Fowler's restudy of (r) in New York City (Labov, 1994). The interrelationship between age grading and apparent time seems to show two different patterns. If a change is ongoing, older speakers as they age may change their speech, to some extent, in the direction of the change. In the case of sociolinguistic variables known to be stable, however, there may be a curvilinear pattern associated with age as well as with social class, whereby speakers in their mid-adult years, more implicated in the 'linguistic market' (Sankoff and Laberge, 1978) may show a greater use of standard variants than is typical of the oldest and youngest speakers.

Second, ever since researchers began using the research design pioneered by Labov, there has been broad agreement that the best way to disambiguate the two interpretations is by examining actual language history. Early researchers tried to find reference points in the past; researchers now can carry out replications of a number of previous sociolinguistic and dialect surveys, adding a real-time component to the study of language change and variation.

Two kinds of longitudinal studies shed light on the relationship among age, apparent time, and real time. All longitudinal research involves comparisons at two points in time, but whereas **trend** studies require resampling the community, **panel** studies follow the same individuals across time. If the goal is to assess language change, trend studies are the only sure way to confirm change. Panel studies, however, are the only way to discover how individual speakers of different ages are involved in linguistic change. Though restudying a community, or following a group of speakers across time, might seem to be a straightforward affair, in fact both kinds of research can involve serious methodological complexities and ensuing problems of interpretation (Tillery and Bailey, 2003). Many researchers have attempted to overcome these problems by combining trend and panel design in various ways.

Two dimensions that are important in determining the course of change are (1) whether we are dealing with change from above or change from below, and (2) the status of the variable within the linguistic system. In Labov's first discussion of the two types of change, he characterizes both stigmatized and prestige features as being relatively simple examples of the pressure of society upon language. These forces are applied from above – they are the product of overt social pressures consonant with the social hierarchy. The process is out in the open for us to observe, in public performances, in the attitudes of teachers in the schools, and in the conscious reactions of some middle class speakers (Labov, 1966).

Change from below, on the other hand, is expressed as a gradual shift in the behavior of successive generations, well below the level of conscious awareness of any speakers. In most cases the shift begins with a particular group in the social structure and is gradually generalized in the speech of other groups. Usually the initiating group has low status in the social hierarchy – otherwise the change would be transformed into overt pressure from above (Labov, 1966).

As far as the linguistic status of the variable or changing feature is concerned, once again this may make a big difference in how it diffuses through the speech community. Whereas isolated features (individual words, perhaps also phonetic innovations that have no implications for the rest of the sound system) may be relatively easy to learn and thus able to diffuse even among older speakers, features that are more structurally implicated (involving more complex constraints and relationships with other elements) may

be much more difficult for older speakers to learn. A preponderance of recent studies deal with changes from above, often in the form of the influence from other dialects (or the standard language). Such features may be more available to adults, who typically have a wider range of contacts than do children.

As in other studies of language variation, the quantitative work reviewed here adopts a model of change that envisages an innovative form such as alternating, or being in competition with an older form. It is worth considering for a moment how this alternation is modeled in the grammar. Quantitative sociolinguistic analysis that is relevant to the diffusion of language change deals with linguistic production, whether in speech or writing. Language that people produce is considered to be based on or generated in accordance with their internalized grammars. If grammars are modeled to include only the information that alternation is possible, then from this qualitative point of view, whether a speaker uses the innovative variant, say, 10% of the time or 90% of the time, the speaker's grammar is the same. In contrast, quantitative sociolinguistic research shows that the use of the variants is governed by constraints, both linguistic and social, that are probabilistic in nature, and holds that these constraints should be modeled in the grammar, that is, there is *inherent variability* in grammars. In studies following Kroch's model of competing grammars (1989), now widely used in corpus-based studies of historical syntax, constraint values have been found to be *constant factors* across the entire course of change, with the only change being in the increased probability of use of the innovative grammar over time. In a sociolinguistic study of the acquisition of the stable sociolinguistic variables (t,d) and (ING), Labov (1989) showed that children as young as five years closely model their parents' constraint probabilities by a process of *probability matching*. In the transmission of variables involved in change, children appear also to attend closely to the constraints of the adult system, but (in the case of sound change) are able to surpass their adult models both phonetically, by going beyond the adult target, and by extending environments in which the innovative variants are used (Roberts, 1997). My conclusion is that changing frequencies, whether on the individual or on the community level, are fundamental to change.

Since 1995 we have seen an increasing number of real-time studies (most frequently, re-studies of sociolinguistic or dialectological research of the 1960s and 1970s). Many of the original studies made apparent time inferences, and for researchers carrying out restudies, it has been tempting to treat these inferences as predictions. However, we should note that there are, in the historical sense, not two but four possible further developments to be observed in the subsequent studies. First, if the original age distribution is repeated at the same level, we interpret the outcome as static age grading. Second, when we note a repeated age gradient but at a higher overall frequency of the change, we interpret the result as a real-time change. The third possibility is that all age groups display the same high level of the variable, which we interpret as the last phase of change going to completion. In this case the trend study should show no further increase on the part of a new generation of young speakers. Since eventually all changes are completed, it may be unreasonable to think that the absence of continuing change constitutes a failed prediction. The fourth possibility is that change is reversed, usually as the effect of stigmatization from above.

In the remainder of this review, we will see how trend and panel studies jointly contribute to a better understanding of what apparent time actually tells us. Table 2 documents the results of all the trend studies I have located in which the original studies found gradient age distributions. Spanning ten countries and seven languages; all but the first were carried out in the last decades of the twentieth century. The first seven studies used strictly trend methodology, whereas studies 8 through 13 included both trend and panel components. Of these, only the trend results are summarized in Table 2 (panel results from these same studies will be discussed below).

Although changes may have been completed, and although we may find a combination of age grading and real time change, in none of the follow-up studies do we find age grading alone. The most important implication of this conclusion is that apparent time is a truly powerful concept in locating the presence of change. In other words, a researcher who locates a gradient age distribution in a new community under study is virtually assured of having identified change, whether or not age grading is also involved.

A thorough discussion of the early-20th-century work of Gauchat and Hermann in Charmey, Switzerland, is found in Labov (1994). Most of the changes identified by Gauchat were verified in real time by Hermann. The longitudinal perspective on Martha's Vineyard is less clear. Whereas a restudy by Pope (2002) found a continuation of the trends discerned by Labov, Blake and Josey (2003) conclude that socio-economic and ideological change on the island has led to different patterns. These differing results serve to underscore how different sampling methods in restudies may lead to interpretive difficulties in discerning longitudinal trends. In any case, neither of these restudies found a replication of the same

Table 2 Results of trend studies on the interpretation of earlier inferences

Study location; variables; date of original study; source of trend information	*Interpretation at Time 1*	*Real Time (Time 2 findings)*
1 Charmey, Switzerland: 5 phonetic changes; 1905; (Labov, 1994)	Apparent time; change from below	Four changes, one stable variable
2 Martha's Vineyard: (ay) nucleus raising; (1961); (Labov, 1965, 1994)	Apparent time; change from below	Possible reversal (Blake & Josey, 2003); possible continuation (Pope, 2002)
3 New York City; (r); (1963); (Labov, 1966, 1994)	Apparent time; change from above	Change plus age grading
4 Norwich; *beer/bear* merger; backing of (e); [ʔ] for /t/; (1968); (Trudgill, 1988)	Apparent time; change from below	Continuing change
5 Norwich; *moan/mown* merger; (1968); (Trudgill, 1988)	Apparent time; change from above	Continuing change
6 Panama City; (ch)-lenition; (1969); (Cedergren, 1987)	Apparent time; change from below	Change; age grading (young adult 'spike')
7 Glasgow; glottal stop; (1970s); (Macaulay, 1977; Stuart-Smith, 1999; (Chambers, 1995)	Age grading	Age grading; continuing change (1990s)
8 Eskilstuna, Sweden; 7 morpho- and morphophonological variables; (1960s); (Sundgren, 2002)	Apparent time; social class effects; change from above	Slower continuing change; age, class and gender effects (1990s)
9 Hanhijoki, Finland; [r] → [d]; (1960s); (Kurki, 2004)	Apparent time; change from above	Continuing change (1989, 1999, 2002)
10 Montreal [r] → [R]; (1971); (Clermont & Cedergren, 1979; Sankoff *et al.*, 2001)	Apparent time; change from above	Continuing change (1984, 1995)
11 Tours, France; *ne*-deletion; (1976); Ashby (2001)	Apparent time; change from below	Continuing change (1995, 1998)
12 Rio de Janeiro, Brazil; several morphological and phonological variables; (1970s); (DePaiva & Duarte, 2003)	Apparent time; change from above and change from below	Continuing change (1990s)
13 Springville, Texas; verbs of quotation; (1987); (Cukor-Avila, 2002)	Apparent time	Continuing rapid change

age gradient isolated by Labov, so there is no suggestion that Labov's initial results were the result of age grading alone.

Trudgill's restudy of Norwich was a strict replication, adding a generation of younger speakers. In addition to verifying the continuing status of the four changes listed in Table 2, Trudgill found two new changes that had barely been present in the community in his original research. Cedergren's restudy of Panama (1987) found both age grading and real time change, as did Fowler's restudy of Labov's New York City department store survey, both discussed extensively in Labov (1994).

In the last pure trend study of Table 2, Stuart-Smith (1999, cited in Marshall, 2003) returned to Glasgow to study the continuing increase in t-glottaling. Marshall's figure 4 (p. 98), which depicts Stuart-Smith's combined results by age and sex, shows an overall increase in glottals as well as a reduction of the difference between adolescents and adults. Apparently both change and age grading were there from the beginning.

In addition to the seven studies of Table 2 that combine trend and panel components, there are others that concentrate on panel comparisons. Several of these deal with change from above, often the impact of other-dialect or standard language features on particular speech communities. To Sundgren's study of Eskilstuna, Sweden (Sundgren, 2002) and Kurki's study of Hanhijoki, Finland (Kurki, 2004) can be added Nahkola and Saanilahti's research on the small town of Virrat in southeastern Finland (2004), and Hernandez-Campoy's (2003) report on a panel study that showed increasing influence of Standard Castilian phonological features. The numerous studies in De Paiva and Duarte (2003) contain a wealth of information on trend and panel comparisons of many sociolinguistic variables in Brazilian Portuguese.

In most panel studies, researchers have found that when there is a change in progress as measured by a trend study, grouped data from the panel shows a modest increase in the direction of the change. When researchers have been able to study individual panelists, this result can typically be decomposed into a majority of speakers who remain quite stable, and a minority who change, often substantially. Those individuals who change in later life are usually in their

20s and 30s, sometimes up to the age of 50, but very rarely have older speakers been found to register significant changes. In our follow-up study of the [r] → [R] change in Montreal French, one older speaker significantly reduced his frequency of use of this change from above after he retired, became ill, and was largely confined to staying at home (Sankoff *et al.*, 2001). Ashby's important research documents another such case with respect to a change from below.

Ashby's trend and panel study deals with the loss of the negative particle *ne* in the metropolitan French dialect of Tours. In his 1976 study Ashby (1981) had established a clear age differential in *ne* deletion, which he interpreted in terms of apparent time, i.e., as a change in progress. Of the 35 speakers distributed according to three socio-professional groups, sex, and age (14–22 vs. 51–64), all three social factors were significant. Whereas the older group used *ne* in 52% of its potential occurrences, the younger speakers used it only 19% of the time. In his 1995 restudy, Ashby (2001) provided real-time corroboration of this interpretation, discovering that the change had accelerated. With a new sample of 29 speakers structured in the same way as the previous one, he discovered that the 51–64 age group now registered only 25%, and the usage of young speakers in 1995 had declined to 14%. Consonant with its status as a change, *ne* deletion was being led by women in 1976 (30% *ne* use vs. 42% for men). However, the sex difference had disappeared by 1995, with the women only three percentage points in the lead (17% vs. 20%, a difference revealed as insignificant by Ashby's multivariate Goldvarb analysis). The panel component of the study comprised ten speakers from 1976 were re-recorded in 1995. As with most other panel studies to date, Ashby found that a majority of speakers (6 of the 10), were quite stable across the 19-year period, registering within 10 percentage points of their previous scores. Of the four who changed, one was anomalous in terms of having gone in the direction opposite to the change: a schoolteacher who registered an increase from 6% to 23% after her marriage to a professional man. The other three speakers were anomalous in a different way: whereas other panel studies have shown that of adult speakers who change, most are younger than 50, Ashby's three were all retired and over 65 by the time of the second study. He attributes their significant declines to the more relaxed style that may be adopted by speakers who are no longer in the world of work (Ashby, 2001).

Panel studies provide a clear overall result: as they age, people register lesser differences from their earlier selves than does the community over the same time interval, as measured by a trend study. This means first, that it must be younger speakers who are in the vanguard of change. Those adult speakers who change are (a) in the minority; (b) concentrated in the younger-age cohorts of adults and (c) make less significant advances than the community as a whole. The second implication of this result is that apparent time must consistently underestimate the rate of change. I will exemplify this last point by considering the real time trajectories from [r] → [R] for 31 Montreal French speakers between 1971 and 1984. Though a majority were stable, a minority of 11, mostly younger, speakers changed over this period in the direction of the change. If the 1971 data were not available and we interpreted the 1984 values according to apparent time, we would assume that, for example, those speakers registering 90%–100% of the innovative variant had begun their lives as children with those same values. However, we know that approximately 1/3 of those speakers had significantly lower values thirteen years earlier, and thus they actually changed over the period. Similarly to the results reported in Nahkola and Saanilahti (2004), those speakers most likely to change were those in the midrange of the change, as opposed to those initially registering close to categorical use of the conservative variant.

Together, trend and panel studies of the past decade have confirmed the validity and usefulness of apparent time as a powerful conceptual tool for the identification of language change in progress. Far from misleading us about the existence of change, apparent time generally underestimates the rate of change. Though the field will continue to be surprised by the light that trend and panel studies can shed on the mechanism of language change – especially as it intersects with speaker life spans – our present synchronic methodology is a powerful lens for interpreting the past.

Aging and Language

J Harwood, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

This article examines changes in language comprehension and production in normal aging, the ways in which lay conceptions of older adults' abilities influence speech directed towards older people, and the effects of that speech on older recipients. Important changes that occur in language as a function of age-related pathology (e.g., Alzheimer's disease) are covered elsewhere (e.g., Kemper and Mitzner, 2001).

Considerable work has focused on language comprehension problems in aging, with a particular focus

on the role of working memory capacity. Correlational evidence suggests that age is associated with problems in understanding complex syntactic structures, and that those problems are largely accounted for by parallel declines in working memory capacity (Norman *et al.*, 1991). Complementary patterns are apparent in language production. Older adults produce less complex syntax, and again, such declines are largely accounted for by declines in working memory (Kemper *et al.*, 1992). Particular problems are experienced with left-branching clauses, and with utterances that include multiple clauses – syntactic structures that put particular strain on working memory. Fast speech rate also results in decreased comprehension for older adults more than for younger adults (Stine and Wingfield, 1987).

Recent research suggests that the association of communication problems with working memory is not a result of the immediate processing in working memory, but rather a function of "postinterpretative processing" (Caplan and Waters, 1996). That is, older adults demonstrate equal initial understanding and processing of language, but demonstrate deficits in the storage and integration of linguistic material into memory for future retrieval and use.

Attention has been paid to older adults' ability to inhibit irrelevant or intrusive thoughts and the implications of this for language production and comprehension. Harsher and Zacks (1988) suggest that a decline in inhibitory ability is part of normal aging, and that it accounts for communication problems in older adulthood. Other scholars assign the association between inhibitory capacity and language use to pathological conditions. For instance, Pushkar, Gold and Arbuckle (1995) suggest that "off target verbosity" in older adulthood is a result of declines in frontal lobe functioning occurring among a minority of older adults. This debate is ongoing.

Less controversy is apparent in examinations of older adults abilities to recall proper names. Considerable evidence indicates problems in this area (Cohen, 1994). Proper names appear to present a particular challenge given their uniquely arbitrary and semantically unelaborated character. Nussbaum, Hummert, Williams, and Harwood (1995) point out that proper nouns have no synonyms, which removes one retrieval route that is used in other situations of retrieval difficulty.

While not strictly language-related, considerable communication problems for older adults are also caused by presbycusis – the normal age-related decline in upper-frequency hearing. While research into other communication problems has generally attempted to control for hearing declines, presbycusis is a somewhat specific pattern of hearing loss that may contribute to some of the problems observed in other research (Schnieder *et al.*, 1994).

The work described above has revealed important problems for older adults' communication, as well as developing theoretical understanding of psycholinguistic processes. However, it has also sometimes conformed to more general notions that aging is about decline, and thus may serve to reify stereotypical notions of aging (Coupland and Coupland, 1990). In the remaining sections, some less pessimistic messages concerning communication and aging are emphasized.

First, the scholars described above are generally careful to note that, many findings reflect small effects that are observable in the laboratory, but have only minor effects in everyday communication (Ryan, 1991). In addition, research has revealed multiple ways older adults compensate for specific deficits, such as by relying more heavily on prosody or processing at a more global level (Stine and Wingfield, 1987, Stine-Morrow *et al.*, 1996). Also, findings of deficits among a group of older adults may be due to some subset of that group who are actually experiencing the early (undetected) stages of some form of dementia, rather than a general pattern of decline across all participants (e.g., note that longitudinal work sometimes shows little age-related change, except among those who experience working memory decline: Kemper *et al.*, 1992). Related to this, many negative effects begin around age 80: Discriminating among age groups within the 'older adult' population is therefore essential.

Second, language and aging research has paid scant attention to what might improve, or remain unchanged, with age as compared with what might decline. Normal aging has no effect on lexical availability or semantic memory (Kemper and Mitzner, 2001), vocabulary increases into old age (Salthouse, 1988), and narrative production improves with age (Kemper *et al.*, 1989). We have little systematic knowledge of older adults' abilities in group decision-making, public speaking, or emotional expression, yet each of these seems open to improvement into late old age. The creative writing skills of older people might also merit investigation as a potential area of improvement in language (Sternberg and Lubart, 2001).

Third, a focus on 'decrement' causes inattention to the positive functions that may be served by what are apparently aberrant behaviors. For instance, Coupland, Coupland, Giles, Henwood, and Wiemann (1988) describe a pattern of "painful self-disclosure" (PSD) among older people – e.g., disclosure to relative strangers about personal issues such as illness or bereavement. It would be possible to interpret this as a sign of egocentrism or a decline in conversational skill. However, Coupland *et al.* (1988) illustrate the

functional nature of PSD for managing age-related face threat.

Fourth, research has begun to pay attention to the social construction of decline and decrement in old age, i.e., decline is created by language use concerning age and language directed towards older adults. Levy (1996) shows that making negative age stereotypes salient leads to less competent behavior (e.g., memory problems). These stereotypes are likely to be activated when older adults are addressed with stereotype-driven language strategies. For instance, patronizing talk to older people (in various manifestations called overaccommodation, elderspeak, secondary baby talk) is documented in numerous settings (Kemper, 1994), particularly institutional settings (Caporael, 1981), and is driven by stereotyped conceptions of aging (Ryan *et al.,* 1986; Hummert *et al.*, 2004). Patronizing speech can result in 'blame the victim' effects (recipients of such speech are perceived to be impaired, even if they are not: Hummert and Ryan, 2001). Varieties of this speech are associated with dependency in institutional environments (Baltes and Wahl, 1996), and older adults in institutional settings become accepting of such speech despite initially viewing it negatively (O'Connor and Rigby, 1996). Ironically, certain elements of the patronizing style (particularly semantic elaboration and reduced syntactic complexity) are helpful to older adults' comprehension, but other elements are harmful, such as prosodic adjustments and reduced sentence length (Kemper and Harden, 1999).

This brief review does not touch on all aspects of language and aging (e.g., paralinguistics of older people's speech, critical approaches, etc.). As noted by Coupland (2004), aging has received less attention than race/ethnicity, gender, class, and regional variation within the sociolinguistic literature on group variation. This is, however, beginning to change, and attention to aging issues is now common in psycholinguistics (Kemper and Mitzner, 2001) and communication (Nussbaum and Coupland, 2004). The theoretical and practical implications of this work are tremendous.

Agrammatism I: Process Approaches

H Kolk, University of Nijmegen, Nijmegen, The Netherlands

Agrammatism is a disorder that leads to difficulties with sentences. These difficulties can relate both to the correct comprehension and the correct production of sentences. That these difficulties concern sentences is evident from the fact that word comprehension and production can be relatively spared. Agrammatism occurs in many clinical populations. For Wernicke's aphasia, for instance, this has been established for both comprehension and production. Agrammatic comprehension has been demonstrated in Parkinson's patients, Alzheimer patients, and children with specific language disorders. However, agrammatism has been studied most systematically in patients with Broca's aphasia, and it is this group that is the focus of this article.

Agrammatism in Comprehension

The large majority of studies on agrammatism in Broca's aphasia have been on comprehension. An important impetus to these studies was the claim made by Zurif and Caramazza in the early 1970s that Broca's aphasics lack all knowledge of syntactical rules. It appeared that these patients were unable to comprehend reversible sentences such as 'the cat that the dog chased was black' (Caramazza and Zurif, 1976). The hypothesis that Broca's aphasics were 'asyntactic' led to three different reactions. The first was that this global characterization ignores the possibility that these patients may all be classifiable as Broca's aphasia but that their underlying deficits may be very different (Badecker and Caramazza, 1985). In support of the claim that agrammatism is not a unitary phenomenon, a number of studies have demonstrated that problems in comprehension can dissociate from problems in production (Miceli *et al.*, 1983); that in production, problems with grammatical morphology can dissociate from problems with syntax *per se* (Miceli *et al.*, 1983); and that there is large variation in the type of morphological errors within a group of patients (Miceli *et al.*, 1989). (It should be noted that the latter findings were obtained from a large group of unselected aphasic patients, both fluent and nonfluent. However, grammatical deficits may manifest themselves very differently in fluent and nonfluent aphasia.) The critique by Badecker and Caramazza has widely been taken as a critique on neuropsychological group studies as such and has led to a substantial shift from group to case studies, particularly in the areas of reading, writing, and naming. Many researchers still insist on the usefulness of group studies in the case of agrammatism, maintaining that these patients share a number of important symptoms that need to be accounted for. A second reaction came from aphasiologists with a linguistic background. It held that instead of a loss of all syntax, only specific subsets of linguistic competence could be lost. In particular, when patients have to understand sentences with noncanonical word order, such as the ones employed by Caramazza and Zurif, they perform at chance, whereas they seem relatively unimpaired with canonical sentences (Grodzinsky, 1989). This approach has led to a large number of linguistically motivated studies of agrammatism, which are discussed in **Agrammatism II: Linguistic Approaches**.

Agrammatism is a disorder that leads to difficulties with sentences. These difficulties can relate both to the correct comprehension and the correct production of sentences. That these difficulties concern sentences is evident from the fact that word comprehension and production can be relatively spared. Agrammatism occurs in many clinical populations. For Wernicke's aphasia, for instance, this has been established for both comprehension and production. Agrammatic comprehension has been demonstrated in Parkinson's patients, Alzheimer patients, and children with specific language disorders. However, agrammatism has been studied most systematically in patients with Broca's aphasia, and it is this group that is the focus of this article.

Agrammatism in Comprehension

The large majority of studies on agrammatism in Broca's aphasia have been on comprehension. An important impetus to these studies was the claim made by Zurif and Caramazza in the early 1970s that Broca's aphasics lack all knowledge of syntactical rules. It appeared that these patients were unable to comprehend reversible sentences such as 'the cat that the dog chased was black' (Caramazza and Zurif, 1976). The hypothesis that Broca's aphasics were 'asyntactic' led to three different reactions. The first was that this global characterization ignores the possibility that these patients may all be classifiable as Broca's aphasia but that their underlying deficits may be very different (Badecker and Caramazza, 1985). In support of the claim that agrammatism is not a unitary phenomenon, a number of studies have demonstrated that problems in comprehension can dissociate from problems in production (Miceli *et al.*, 1983); that in production, problems with grammatical morphology can dissociate from problems with syntax *per se* (Miceli *et al.*, 1983); and that there is large variation in the type of morphological errors within a group of patients (Miceli *et al.*, 1989). (It should be noted that the latter findings were obtained from a large group of unselected aphasic patients, both fluent and nonfluent. However, grammatical deficits may manifest themselves very differently in fluent and nonfluent aphasia.) The critique by Badecker and Caramazza has widely been taken as a critique on neuropsychological group studies as such and has led to a substantial shift from group to case studies, particularly in the areas of reading, writing, and naming. Many researchers still insist on the usefulness of group studies in the case of agrammatism, maintaining that these patients share a number of important symptoms that need to be accounted for. A second reaction came from aphasiologists with a linguistic background. It held that instead of a loss of all syntax, only specific subsets of linguistic competence could be lost. In particular, when patients have to understand sentences with noncanonical word order, such as the ones employed by Caramazza and Zurif, they perform at chance, whereas they seem relatively unimpaired with canonical sentences (Grodzinsky, 1989). This approach has led to a large number of linguistically motivated studies of agrammatism, which are discussed in **Agrammatism II: Linguistic Approaches**.

The Mapping Hypothesis

A third type of reaction to the claim that 'grammar was gone' in agrammatism was that it is not so much the knowledge of grammatical rules that is impaired but the processing of this knowledge. The processing approach started with the seminal study by Linebarger *et al.* (1983), who observed that a number of agrammatic patients who performed at chance in comprehending reversible sentences with noncanonical word order were unimpaired in judging the grammaticality of the sentence. This dissociation led the authors to conclude that there could not be a loss of competence in agrammatism, as proposed by Caramazza and Zurif. Two possible accounts were suggested. The first was that the deficit did not relate to syntax as such but to the operations by which the syntactic level of representation (S-structure in transformational theory) was mapped onto the semantic level (D-structure) in order to assign thematic roles. Such mapping would be necessary for comprehension but not for grammaticality judgment; hence the dissociation. A second account had to do with mental resources. It is a well-known empirical phenomenon that carrying out two tasks simultaneously is more difficult than performing either task by itself – the so-called 'dual-task effect.' Comprehension can be regarded as a double task because it involves both syntactic and semantic processing, whereas grammaticality judgment presumably only depends on syntactic processing. A follow-up study provided evidence against the resource hypothesis (Schwarz *et al.*, 1987). In this study, patients were asked to judge the plausibility of sentences. A comparison was made between simple actives, complex active sentences, and sentences with a noncanonical word order (e.g., passives and object gaps). Simple actives elicited relatively few errors, indicating that the problem was not with mapping as such. Sentences with a noncanonical word order elicited substantially and significantly more errors. This was attributed to the lack of syntactic transparency: Argument position in D- and S-structure is not the same, so mapping is complicated. Surprisingly, although complex sentences were somewhat more difficult than simple ones, the difference was not significant. This led to authors to reject the possibility that the dissociation between comprehension and grammaticality judgment was due to the cognitive resources of these patients being too limited to carry out two language tasks at once. The mapping hypothesis would therefore be the most appropriate account of agrammatic comprehension.

Kolk and Weijts (1996), however, argued that the way complexity was defined in the Schwartz *et al.* (1987) study may be less appropriate. To obtain a maximal complexity difference with a simple sentence, one should embed a relative clause between the agent noun phrase (NP) and the verb of this simple sentence, and this rarely occurred in the Schwartz *et al.* (1987) materials. When single-clause sentences were compared to sentences with center-embedded clauses, a significant complexity effect was obtained. It was concluded that (1) the resource hypothesis could not be rejected, and (2) in addition to word order, embedding is an important factor in agrammatic comprehension.

Of course, the mapping hypothesis was not ruled out by these results either. If one could think of the mapping process becoming more error prone, not only in the case of a noncanonical word order but also in the case of embedding, a mapping hypothesis could account for Kolk and Weijts's results. Such an hypothesis would be a resource limitation hypothesis, not a general one, as originally proposed, but a specific one related to the process of mapping syntactic structure onto thematic roles. Further research with the plausibility paradigm indeed led to such an hypothesis. Saffran *et al.* (1998) found that even single-clause sentences could pose serious difficulties to agrammatic patients. In particular, the patients found it very difficult to reject a sentence such as 'the painting disliked the artist,' performing just above chance. This is all the more remarkable since these sentences are nonreversible and active. Active nonreversible sentences generally produce very low error rates in a sentence picture matching task. It was argued that with these sentences, there is a strong bias to accept the interpretation indicated by the individual word meanings (an artist disliking a painting). Unimpaired individuals escape from this bias because syntactic analysis eliminates the interpretation that is inconsistent with the syntactic structure. In aphasics, this correcting influence is reduced "because of a pathological decrease in the spread of activation from the syntactic constituents to the units that represent syntactic roles" (Saffran *et al.*, 1998, p. 290). [Kolk *et al.* (2003) present an event-related potential (ERP) study with normal persons, which represents a follow-up of the Saffran *et al.* (1998) study. The results of this study indicate that in normal persons semantic factors can overrule syntactic ones, even in unambiguous sentences.] Therefore, the authors maintained that the locus of the impairment is in the mapping stage. The nature of the impairment is conceived of differently: It has to do with resources. With this hypothesis, it is possible to account not only for the semantic bias effect observed in this experiment but also for the greater difficulty of sentences with a noncanonical word order in the traditional sentence picture matching tasks. Due to the fact that the first

NP frequently carries the agent role, there is a bias both in normal and in aphasic people to interpret the first NP as an agent. As a consequence of their resource limitation, agrammatic patients have an even stronger bias to take the first NP as the agent of the verb, hence the canonicity effect.

The Resource Limitation Hypothesis

If indeed some sort of resource limitation is the underlying cause of agrammatism, as suggested by the outcome of the Saffran *et al.* (1998) study, it becomes interesting to again consider grammaticality judgment. Hartsuiker and Kolk (1998) used a word monitoring paradigm to study the detection of grammaticality and found that patients were able to detect ungrammaticalities in simple but not complex sentences. The normal participants did not show this complexity effect. In a recent ERP study, however, with subject and object-relative sentences, an effect of complexity on grammaticality detection was observed in normal participants (Kolk *et al.*, 2003).

Further evidence for the presence of a resource limitation in agrammatism comes from studies on the interpretation of pronouns. For the proper interpretation of pronouns, it is essential that proper reference is made to persons, places, objects, or events in the contextual environment. This can only occur by means of integration of syntactic and discourse-related operations. From a resource-limitation standpoint, this means that pronoun interpretation should pose difficulties for agrammatic patients, particularly if the discourse operations are relatively complex (for a review, see Avrutin, 2000). In one study, it was found that sentences such as 'Who did the tiger chase?' were much less impaired than sentences such as 'Which lion did the tiger chase?' This contrast was explained by assuming that in the second sentence, reference is made to items, presupposed in the context, whereas in the first sentence there is no such presupposition. Difficulties with pronouns can also be demonstrated in sentences that, unlike the ones presented previously, do not involve argument movement. For instance, patients are much impaired when they have to establish reference for a pronoun in the presence of two possible antecedents: for example, 'First John hit Bill and than Mary hit him.' Similarly, more errors are made on nonreflexive (e.g., 'Is Mama Bear touching her?') than on reflexive pronouns (e.g., 'Is Mama Bear touching herself?'). The argument here is that with the reflexives, reference is to a unit present in the sentence itself – Mama Bear – and is therefore a purely syntactic operation. In the case of nonreflexive pronouns, on the other hand, reference has to be made to units present in the discourse and therefore requires syntax–discourse integration (Avrutin, 2000).

The Timing Hypothesis

Regarding the nature of the resource limitation, the most frequent approach has been to characterize it in terms of time (for a review, see Kolk, 1995). This means that the underlying deficit would relate either to a fast decay or to a slow retrieval of syntactic information. Either of these deficits would lead to a reduced period of time in which syntactic information is available for processes such as tree building the assignment of thematic roles, referential operations, and so on. This proposal has been implemented in a computational model that simulated the effects of varying degrees of fast decay or slow retrieval on tree building, assuming that a disruption of tree building would also negatively affect role assignment (mapping) and reference operations (syntax–discourse integration). The model was able to simulate the effects of variation in degree of severity and syntactic complexity on agrammatic error profiles, obtained in two earlier studies. Simulation was only successful when the timing disorder was assumed to affect syntactic phrasal categories and not when it affected function word categories alone. When phrasal categories were involved, it did not matter whether decay or retrieval rates were affected. The model bears close resemblance to the model of agrammatic comprehension by Haarmann *et al.* (1997). In this model, a limitation in the size of a pool of activation is responsible for agrammatic comprehension. This limitation leads to either a 'reduced efficiency,' which amounts to slower computation, or a reduced maintenance, comparable to fast decay. [Outside the sentence domain, Dell *et al.* (1997) simulated word production deficits in fluent aphasia using a similar contrast. The simulated deficits could consist of either 'a reduced connection strength,' leading to slower activation spreading, or fast decay. Interestingly, a later version of the model assumed only a single deficit – reduced connection strength – affecting either the phonological or the semantic level (Foygel and Dell, 2000).] The Haarmann *et al.* (1997) model constitutes an elaboration of the capacity model for normal sentence comprehension of Just and Carpenter (1992). [This model has been criticized by Caplan and Waters (1999), who argued for a subdivision of verbal working memory into one for automatic (e.g., structure building and role assignment) and one for controlled language processing (pragmatic and discourse related). Broca's aphasics should suffer from an impairment in the first type of working memory. From the evidence reviewed previously, it seems clear that

Broca's aphasics are impaired on both syntactic and discourse-related operations. Furthermore, Kolk *et al.* (2003) present ERP evidence from normal people against this subdivision.] This model is about differences in the size of the activation pool within the normal population, between persons with a high versus a low working memory capacity. This implies that according to this theory, the agrammatic patients are not qualitatively but only quantitatively different from normal language users: They are at the lower end of a normal distribution of language capacity. Support for this hypothesis was provided by Miyake *et al.* (1994), who showed that when normal persons are presented with a large set of sentences of varying complexity at a very rapid rate, the error profile is highly similar to what has been found with aphasics.

A number of experimental studies have provided evidence for the timing hypothesis, particularly for the notion that syntactic processing is slowed down. This was done by means of various on-line techniques in which stimulus-onset asynchrony was manipulated, such as the syntactic priming paradigm (Kolk, 1995) and the crossmodal priming paradigm. Swinney *et al.* (1996) employed a crossmodal priming paradigm to study reactivation of moved arguments at their canonical site. They found that Broca's aphasics failed to show evidence for such reactivation. This failure is important because it could underlie the difficulties these patients have in comprehending sentences with moved arguments. Research, however, suggests that the failure is only a temporary one. When probed at later points in time, it appeared that patients did not show evidence for reactivation at the canonical site, nor at 300 ms after this site; at 500 ms, however, they did demonstrate reactivation of moved arguments.

Other support for the timing hypothesis comes from studies on ambiguity resolution. Research with normal persons has demonstrated that the interpretation of an ambiguous word is affected by the context in which it occurs. Therefore, in a sentence such as 'He made a phone call to the bank,' only the money-related meaning is activated. In an ERP study with Broca's aphasics, however, evidence was found for activation of both the appropriate and the inappropriate meaning (in the example given, the meaning related to river) at an interstimulus interval of 100 ms. After 1,250 ms, however, only the appropriate meaning was still active.

Two studies employed a word-monitoring paradigm and failed to find evidence for slow activation. This failure may have something to do with the nature of the word-monitoring paradigm. The priming results presented previously suggest that the delay may be as small as 500 ms. Given the fact that in these two studies, one or two other words intervened between the word containing the violation and the word to be monitored, the word-monitoring paradigm may not be sensitive enough to pick up a delay of this size.

Agrammatism in Production

Symptoms of agrammatic production have traditionally been assessed by means of analysis of spontaneous speech (Goodglass and Kaplan, 1983). Three main types of symptoms of spontaneous speech have been established in this way. The first is a reduced variety of grammatical form. The sentences that are produced have little subordination or phrasal elaboration. Because these symptoms relate to sentence form, we call them syntactic symptoms, where the term 'syntactic' is used in a purely descriptive way. Second is the omission of function words – articles, pronouns, auxiliaries, copulas, prepositions, and the like – and inflections. All these symptoms relate to grammatical morphology and are therefore referred to as morphological. The third is a slow rate of speech or nonfluency, referred to as the rate symptom. Whereas the previous symptoms have been established for English-speaking patients, similar symptoms occur in many other languages (Menn and Obler, 1990).

There has been some discussion in the literature on whether syntactic symptoms and morphological symptoms are caused by two independent deficits. This discussion was instigated by the case study of Miceli *et al.* (1983), who described an Italian-speaking patient as having "an almost pure morphological disorder" (p. 75), with syntax being almost entirely spared. Such a dissociation would indicate the existence of two independent deficits, a morphological and a syntactic one. However, the speech of this patient was characterized by a high number of nonfinite clauses, in which either the verb was lacking or the verb was used in the form of an infinitive or a past participle. For such clauses, it is difficult to argue that they are syntactically 'normal.' At least for languages such as English, Dutch, and German, a normal sentence must contain an inflected verb. In a further effort to find support for this double-deficit hypothesis, Rochon *et al.* (2000) conducted a large-scale factor analytic study that failed to support the hypothesis. Instead of a dissociation between syntactic and morphological symptoms, there was a dissociation between syntactic symptoms and symptoms related to inflection omission, on the one hand, and symptoms related to function word omission, on the other hand. It seems that the case for the existence of two

independent grammatical deficits has not been made in a convincing way.

Variability of Symptoms

It is important to realize that these symptoms do not appear in an all-or-none fashion. Some patients show these symptoms slightly more often than a normal speaker, whereas other patients have them in almost all their utterances. A study of 22 Dutch-speaking Broca's aphasics examined the frequency of syntactic, morphological, and rate symptoms. With respect to syntactic symptoms, a mean percentage of embedded clauses of 6% was observed compared to 22% in a normal control group, but the frequency of this syntactic symptom varied from 0 to 21%. The same variability was apparent in the omission rate of grammatical morphology: It varied from 98 to 10%, almost as low as that for the control group, who omitted 8%. Finally, variability was also present in the rate symptom, which ranged from 23 to 90 words per minute, with the control group producing an average of 145 words per minute. Later work with a group of 37 English-speaking patients demonstrated similar variability (Rochon *et al.*, 2000). As Rochon *et al.* (2000) indicated, there appears to be continuity on syntactic, morphological, and rate symptoms, both within the patient group and between the patient group and the normal controls. The implications of these observations are twofold. First, there is between-patient variation in the degree to which symptoms are present in individual patients. Second, because very few patients exhibit a particular symptom 100% of the time, there is within-patient variation: A symptom may be present on one occasion and fail to appear on other occasions. This probabilistic character of aphasic symptoms is not limited to sentence production. As noted by Goodglass (1993), inconsistency is the hallmark of aphasic behavior: A word that is appropriately produced or understood at one time will go wrong the next time and vice versa. At the same time, inconsistency is not a necessary outcome of brain dysfunction. It is not present in Alzheimer's disease, for instance, in which if a particular word is no longer understood, it will remain so on subsequent trials. This means that the variability of aphasic symptoms needs to be accounted for, as much as the symptoms.

The Timing Hypothesis

The most natural way to account for both within-patient and between-patient variability is to assume a resource limitation rather than a loss of some specific operation or set of operations. [Note that Friedmann and Grodzinsky (1997) made an attempt to account for between-patient variability (severity) by assuming loss of nodes at various heights in the syntactic tree. A loss at the level of tense or agreement node would lead to difficulties with inflection, whereas a loss at the level of the complementizer node would leave the ability to inflect intact but would make it possible for the patients to produce embedded clauses. This hypothesis predicts that when the agreement node is damaged, patients would only produce infinitives, in the case that their language has such infinitives. Data from Hofstede and Kolk (1994), however, indicate that the number of infinitives in the spontaneous speech of Dutch-speaking Broca's aphasics varies continuously: There is no bimodal distribution of patients who produce infinitives with a normal frequency and patients who produce infinitives in every utterance.]

As noted previously, to account for agrammatic comprehension, the resource limitation hypothesis has typically been worked our in terms of time, and this is also the case for agrammatic production. According to this hypothesis, fast decay or slow retrieval of grammatical information would disrupt the buildup of a syntactic tree. Such a disruption would harm not only comprehension but also production of sentences.

How does the temporal window hypothesis deal with variability? Between-subject variability was successfully implemented in the computer model referred to previously (Kolk, 1995) by making average decay or retrieval rates differ between simulated patients. Within-patient variability was simulated by making these rated vary stochastically around a mean.

To test applicability of the timing hypothesis to agrammatic production, Hartsuiker and Kolk (1998) employed a syntactic priming paradigm. In this paradigm, the participants repeated a sentence (e.g., 'The church was struck by the lightning'). After this, they were presented with a picture that they had to describe in one sentence (e.g., a picture of a cat chasing a dog). Normal participants tended to do this by employing the sentence form just presented to them. They did so despite the fact that they were unaware of the purpose of the experiment since they were told they were engaged in a study meant to test their memory for pictures. In a study of 12 Dutch-speaking agrammatics, the investigators found normal, and in one condition even better than normal, priming. Of particular interest are the results obtained with the production of passives. In the spontaneous speech of these patients, passives were extremely rare. In a picture description pretest, there was only a single occurrence of a passive construction in the whole group. After priming, however, passives appeared to be deblocked: 7 of 12 patients produced one or more passive constructions. These results fit the timing

hypothesis quite well. If the computation of the constituent structure is delayed, priming speeds up this computation because the structural units have already reached a certain level of activation due to the previous repetition of this structure and it will generally take less time to bring these units to threshold.

According to the timing hypothesis, all operations that are necessary for planning a grammatical sentence have to be carried out within a limited amount of time. This means that not only syntactic but also conceptual or message-level operations could reduce the chance of computational simultaneity. Hartsuiker *et al.* (1999) carried out two experiments with Dutch agrammatic speakers in which they studied agreement inflection production. They drew upon a paradigm in which participants were presented with sentence fragments that had to be repeated and completed (e.g., 'The king of the colonies-was powerful'). One manipulation concerned the conceptual number of the head noun. This could be singular, as its grammatical number (e.g., 'the baby on the blankets'), or it could be plural (e.g., 'the label on the bottles'), unlike its grammatical number. In the latter example, although the head noun is grammatically singular, it is in fact referring to a multitude of labels, one on each bottle. Experiments with normal participants have demonstrated effects of conceptual plurality. In particular, they observed that in sentences with a head noun, which is grammatically singular but conceptually plural (e.g., 'the label on the bottles'), more agreement errors were made than in sentences without such a mismatch (e.g., 'the baby on the blankets'). This indicates that normal speakers take conceptual information into account when constructing subject–verb agreement. In two experiments with agrammatic speakers and normal controls, Hartsuiker *et al.* (1999) replicated this conceptual number effect in Dutch for the normal but not for the agrammatic speakers. In fact, in the second experiment, which was better controlled, the agrammatics made fewer agreement errors in the mismatch condition than the normal controls. A subsequent comprehension test showed normal sensitivity in the agrammatics to the conceptual number variable. It was concluded that agrammatic speakers do not take into account conceptual information while constructing subject–verb agreement. They are unable to reach computational simultaneity of conceptual and syntactic information. This result parallels the difficulties agrammatic patients have with the interpretation of pronouns, which were discussed previously. Both appear to stem from the necessity to integrate two levels of representation: the syntactic and the discourse level in the case of comprehension and the syntactic and the message level in the case of production.

The Ellipsis Hypothesis

Ellipsis refers to well-formed incompleteness. So when a normal speaker utters 'everybody out,' he or she does not make a speech error. Linguistically, ellipsis can be defined by the absence of tense or finiteness. This means that in these utterances either a verb is lacking or an uninflected verb is used. Indefrey *et al.* (2001) studied the production of these constructions by German-speaking participants in a positron emission tomography study. Compared to complete sentences, the ones lacking finiteness elicited less brain activation. The area in which the blood flow response varied was the operculum in the left hemisphere, but in a replication the variation was observed in Broca's area. The ellipsis hypothesis holds that agrammatics overuse these little demanding elliptical constructions, presumably because they lack the capacity to generate sufficient brain activation to produce their complete counterparts. Various kinds of evidence support this hypothesis (Kolk, 1995). First, features of normal ellipsis – related to word order, subject omission, inflection omission, and so on – are also characteristic of the nonfinite constructions of agrammatic speakers. Second, categories of nonfinite constructions obtained from normal speakers, aphasics, and 2- and 3-year-old children have very similar distributions (Kolk, 2001). Third, substantial task effects are observed when spontaneous speech is compared to various kinds of picture description tasks, with the general trend being fewer omissions and more substitutions of grammatical morphology.

Task effects can be very large. For instance, a Dutch-speaking patient was observed who omitted finiteness in approximately 80% of his utterances in his spontaneous speech, and this omission rate decreased to almost zero not only in a picture description task but also in a condition in which the patient was requested to 'speak in complete sentences.' However, this shift to more complete sentences had a cost: It led to an increase in rate symptoms, as the patient paused longer between words and repeated more words. It may seem, therefore, that the rate symptoms are related to both the syntactic and the morphological symptoms. They would reflect a process of corrective adaptation to the timing deficit: A representation that is too complex disintegrates prematurely and the patient attempts to covertly repair the representation (for a further test of this hypothesis, see Oomen *et al.*, 2001).

Conclusion

Studies on agrammatic comprehension indicate the existence of a processing bottleneck at the syntactic level. Effects of this bottleneck manifest themselves

in tasks that primarily depend on the syntactic level but also in tasks that require the integration of this level with discourse and message levels of representation. The processing bottleneck appears to relate to temporal aspects of language processing.

Agrammatism II: Linguistic Approaches

Introduction

The term agrammatism is used in a rather general way in the following discussion to refer to syntactic deficits of a sort that have been observed in Broca's aphasia. The term is used only to pick out certain phenomena as a focus of inquiry, without implying any exclusionary criteria or limitations on what counts as agrammatism or what does not. Agrammatic data form one piece of the neurolinguistic enterprise and are most useful only in conjunction with other data (from neuroimaging, from behavioral studies, and so forth).

The phenomena that constitute the focus of inquiry here are specific attempts to characterize the patterns of sparing and loss in Broca's aphasia in terms of linguistic theory. Although it may seem self-evident that any understanding of language sparing and language loss can only be as good as our theory of language, the fact is that the majority of researchers who have investigated agrammatism have ignored linguistic theory or have simply been unaware of its existence. Partly this is because many of those interested in agrammatism have primarily medical or clinical interests, partly because agrammatism predates linguistic theory by about a century, and partly because of sundry pragmatic considerations that need not detain us. Despite neglect in some quarters, linguistic theory nevertheless has been brought to bear on agrammatic phenomena, and a number of models have been proposed.

Before looking at some of these models, first it is necessary to consider what the nature of the enterprise is. Let us say that we have two bodies of knowledge that we may refer to, in broad terms, as brain theory and linguistic theory. In what ways can the study of agrammatism help to unify these two bodies of knowledge? Agrammatism involves abnormal brains and abnormal language, so we may rephrase the question as two related questions: (1) Do we expect to learn more about normal brains by looking at agrammatism?; and (2) Do we expect to learn more about the normal language faculty by looking at agrammatism? Answering either question in the affirmative would inevitably involve linking the two bodies of knowledge.

A sample of linguistic models of agrammatism is described in the next section, and thereafter this article returns to discussing these basic questions.

Linguistic Models of Agrammatism

Comprehension and production have been treated separately in research on agrammatism. This is because a number of Broca's aphasics who are impaired in their production but reportedly unimpaired in their comprehension have been identified. Therefore, this distinction is maintained here.

Comprehension

Quite a number of models of agrammatic comprehension have been proposed (Caplan and Futter, 1986; Druks and Marshall, 1995; Friederici and Gorrell, 1998; Grodzinsky, 1995; Hickok and Avrutin, 1995; Hickok *et al.*, 1993; Linebarger *et al.*, 1983; Mauner *et al.*, 1993; Piñango, 2000; among others). More or less overtly, most of these models seek to partition the sentences that Broca's aphasics are good at from those sentences that they have difficulty with along a divide suggested by linguistic theory. The idea is that this will be informative about which aspects of language the impaired brain can no longer process, information that can potentially feed into both brain theory and linguistic theory. Just two of these models are discussed: the Trace-Deletion Hypothesis (Grodzinsky, 1995) and the Double-Dependency Hypothesis (Mauner *et al.*, 1993).

This is not a random selection. The selection is intended to contrast a model that is constrained by linguistic theory and one that introduces nontheoretical components. This will serve to clarify what is important in the effort to find links between two bodies of knowledge, keeping our eyes on the prize.

Caramazza and Zurif (1976) showed that Broca's aphasics suffer from certain selective impairments in comprehension. At the time, this was a surprising finding because it had been believed for over a century that their comprehension was unimpaired. The fact that the disorder was selective is what made it potentially interesting from the perspective of linguistic theory. Caramazza and Zurif reported that on reversible sentence–picture matching tasks, Broca's aphasics did not know who was doing what to whom (who was the Agent and who was the Theme) in passive constructions and object-relative constructions – their performance was random. By contrast, they knew who was doing what to whom in active sentences and subject-relatives, where their performance was above chance. This pattern has since been observed very frequently in Broca's aphasics, such that it is now considered 'core' (though there is controversy regarding just how uniform this is).

One of the first attempts to characterize this core agrammatic pattern was the Trace-Deletion Hypothesis.

The Trace-Deletion Hypothesis (TDH)

The TDH is in two parts. The first specifies that in an agrammatic representation that is otherwise normal, traces in Θ-positions are deleted. This has the consequence that moved referential NPs lack information about thematic roles (like Agent or Theme) since that information is carried by the trace. The second part of the TDH indicates how NPs that lack a thematic role are assigned a role. The claim is that they are assigned a role by way of a default strategy: assign a referential NP a role by its linear position (e.g., first NP = Agent) if it does not already have a Θ-role (Grodzinsky, 1995). To see how this works, consider the following passive sentence:

1. $[\text{The boy}]_i$ was chased t_i by the girl
   Theme Agent

In an unimpaired representation, the NP (*the boy*) moves from the object position to the front of the sentence. This movement leaves a trace (*t*) behind, in the object position. The role of Theme is assigned to the position occupied by the trace and conveyed to the moved NP via a chain shown by the coindexations (*i*) in (1). Now, let us turn to what happens in an agrammatic representation:

2. [The boy] was chased * by the girl
   Default agent Syntactic agent

Lacking trace (*), the chain is disrupted and the moved NP (*the boy*) is assigned the Agent role by the default strategy. The NP in the *by* phrase, which is not thought to have undergone movement, is assigned the Agent role in the normal way, syntactically. The upshot is that the representation contains two NPs, each competing for the role of Agent. On a standard sentence–picture matching task, the patient must guess which NP is Agent, and random performance follows, consistent with fact.

The TDH has been subject to severe criticism. A major flaw is that the deletion of trace does not, in fact, divide spared and impaired structures. Traces occur in virtually every sentence, but agrammatics do not have problems with virtually every sentence. To effect the division, in every instance, requires the effective agency of the totally atheoretical default strategy. There is no theory of strategies, and strategies do not form part of linguistic theory. The deletion of trace, on its own, has no consequences, yet trace is the only part of the TDH that is motivated by linguistic theory. Relevant consequences (i.e., partitioning the data into sentences agrammatics can understand and those they cannot) arise only by virtue of the atheoretical default strategy. Thus, if the aim of the study of agrammatism is to contribute to the linking of two bodies of knowledge, brain theory and linguistic theory, the problem is that, under the TDH, linguistic theory does not in fact do much work.

The Double-Dependency Hypothesis (DDH)

Partly motivated by the shortcomings of the TDH, the DDH (Mauner *et al.*, 1993) sought to do away with any reliance on atheoretical strategies to partition agrammatic data and to account for those data entirely in terms of linguistic theory. At the heart of the proposal is the observation that there is a class of dependency relations, namely, those obtaining in syntactic chains that are assigned only one Θ-role, and that in relations of this kind, in agrammatism, the dependency between a referential NP and the foot of the chain is disrupted. This amounts to a loss of a constraint on coindexation. In sentences where there are **two** such dependencies, confusion arises over which NP is coindexed with what. Because the coindexation is semantically ambiguous, thematic role assignment is also ambiguous. This has the consequence that agrammatics must guess who is doing what to whom. By contrast, where there is only **one** such dependency, there is no possible ambiguity, so agrammatic interpretation should be normal. For an example with two dependencies, consider the following passive sentence:

3. $[\text{The dog}]_i$ was $\text{bitt}[\text{en}]_k$ t_i by $[\text{the cat}]_k$

In this sentence, the two dependencies correctly coindexed in a normal representation are $<[\text{the dog}]_i, t_i>$ and $<\text{en}_k, [\text{the cat}]_k>$. The referential NP, *the dog*, and the foot of its chain, the trace *t*, form one dependency. The second dependency is between the referential NP, *the cat*, and the foot of its chain, the passive morphology *–en*. In an agrammatic representation, however, the ambiguous interpretation would permit not only the correct coindexations, as above, but would also allow the anomalous coindexations: $<[\text{the dog}]_i, \text{en}_k>$ and $<t_i, [\text{the cat}]_k>$.

The DDH succeeds in accounting for the core data (actives, passives, subject-relatives, and object-relatives) and a wide range of other data without resorting to strategies. Interestingly, this model survives stern crosslinguistic tests, with a variety of reversals of canonical word order, where all other

models that incorporate linear-based strategies fail (Beretta, 2001).

Production

Traditional accounts of production deficits in agrammatism focus on the reduction in the range of syntactic forms that are available for deployment, the slow, effortful speech that is typically observed, and the loss or substitution of morphology (particularly function words and bound inflectional morphemes). Only the morphological deficit has received sustained attention in linguistic models, so here I describe two recent attempts to capture those phenomena: Hagiwara's (1995) model and Friedmann's (2001) tree-pruning hypothesis, both very similar models. The initial insight is due to Ouhalla (1993), who proposed that agrammatics lack all functional categories. Functional categories form the higher branches of the syntactic tree and Ouhalla's view was that nothing above VP survived in agrammatism. This turned out to be too all-or-nothing a characterization to accommodate the frequently observed sparing in many agrammatics of some functional categories. The models of Hagiwara and Friedmann are more flexible.

Hagiwara's Model Like Ouhalla, Hagiwara's (1995) model locates agrammatic impairment in functional categories, but rather than lopping off all of the syntactic tree above VP, the model identifies a level for each agrammatic subject. Wherever in the tree that level is found to be for an individual, all elements dependent on nodes above it are lost and those dependent on nodes below it are spared. For example, Hagiwara reported Japanese subjects who had lost NegP but who retained the higher CP node. The model is framed in terms of increased processing costs for each application of a structure-building operation known in current linguistic theory as Merge (Chomsky, 1995).

Friedmann's Model The tree-pruning hypothesis, like Hagiwara's, finds the level in the tree indicated by each individual agrammatic subject's performance on a range of tests. Friedmann (2001) reported a group of Hebrew-Arabic-speaking agrammatic subjects who made many errors of Tense but relatively few of subject–verb agreement. She argues that other studies in a range of languages offer a degree of support for this finding. She explains these findings by reference to a syntactic tree in which agreement (AgrP) is below Tense (TP). Agrammatics, it is suggested, cannot project to the higher Tense node.

What Does the Study of Agrammatism Tell Us about Brains or about Language?

What Does Evidence Organized by Linguistic Models of Agrammatism Reveal about Brains?

Brain theory deals with how brains get to accomplish the work they must do, from autonomic and somatic function to cognitive function. This work is accomplished by, among other things, patterns of firing of assemblies of feature-tuned neurons in particular regions. These patterns, it is thought, may constitute a neural code. The effort is to discover what the spatio-temporal neural codes are for any given function and how they instantiate behaviors. How can the study of agrammatism help with this? To the extent that we have a coherent theory of the normal language faculty, and to the extent that we have characterized abnormal agrammatic language correctly, then, whatever spatial and temporal neural information we find that produces observed behaviors should be relevant.

As a simple example, if someone acquires brain damage to a specific area, and if there are certain selective language deficits that we can observe in this person and which we can characterize properly, then this suggests that the lesioned area is implicated in the processing of those specific aspects of language that are compromised.

In this light, let us consider a contribution that comprehension models of the sort described above might reasonably make. Experiments testing these models involve Broca's aphasics who have lesions minimally encompassing Broca's area and its vicinity. Aspects of linguistic theory have been shown in some of these experiments to yield the requisite partitioning of data. The relevant aspects are a class of referential dependency relations (which involve more than trace–antecedent relations). Processing these dependency relations is problematic in agrammatism and is responsible for the observed pattern of sparing and loss. Therefore, it might be posited that Broca's area is implicated in the processing of these dependency relations. To the extent that this claim is justifiable, it constitutes an initial attempt to link something of what we know about brains (function is localized) and something of what we know about language (it involves the processing of a broad class of dependency relations).

The neuroimaging record lends some support to this view (e.g., Caplan *et al.*, 1999; Stromswold *et al.*, 1996; Just *et al.*, 1996), though the picture is, unsurprisingly, far more complex (Caplan *et al.*, 2001). The processing of dependencies apparently also implicates other areas of cortex. In addition, many other linguistic (and nonlinguistic) processes implicate the left inferior frontal cortex. Thus, whereas

functional neuroimaging experiments suggest that a broad range of linguistic processing involves many brain regions, functional magnetic resonance imaging (fMRI) and positron-emission tomography (PET) studies coupled with the data from agrammatism confirm the importance of Broca's area and environs in the processing of relevant dependency relations.

The combination of data from well-motivated fMRI and PET experiments and data from principled studies of impaired subjects may be seen as preliminary, but it holds out promise for the future.

Apart from localization, agrammatic data, coupled with magnetoencephalography (MEG) and electroencephalography (EEG) experiments, ought to be revealing about some aspects of the temporal coding of language.

In principle, finding out more about brains by investigating agrammatism is at least possible. If we wish to know how a brain computes language, we must examine it computing language – and selectively failing to compute language in the normal ways.

What Does Evidence Organized by Linguistic Models of Agrammatism Reveal about Language?

It is quite common to read in the literature on agrammatism that agrammatic data provide a constraint on linguistic theory. Linguistic theory, it is asserted, must be compatible with the evidence from agrammatism. This is an interesting point of view, but one that needs to be thought through carefully. For instance, what happens if there is clear evidence from an agrammatic subject that conflicts with clear grammaticality judgment evidence? Is one form of evidence to be privileged over the other? Often, it is assumed that agrammatic data should be privileged because it is in some undefined sense more 'real' than grammaticality judgment data. But this view lacks merit. Any reasonable scientist will take evidence wherever it is to be found, and judgment data are the most obvious data presenting themselves to linguists. Grammaticality judgments are controlled experiments every bit as much as experiments with agrammatics. Any given experiment, whether it uses judgments of grammaticality, reaction times, or neuroimaging technologies, may yield findings that are either relatively clear or not, or may be based on predictions that follow from theory or not, or may suffer from methodological problems or not. Thus, experiments yielding different kinds of data may be well designed and executed or not, but there is nothing more real about one kind of data than another.

If agrammatic data ordered by linguistic theory are to be used to constrain linguistic theory, it is axiomatic that the agrammatic data actually **be** ordered by linguistic theory (and not by an atheoretical strategy, for example). Some models of agrammatism honor this simple logical requirement, but not all of them do. To the extent that this requirement is observed, agrammatic data can, in principle, be useful in testing linguistic theory, but it is worth stressing that the value of any experiment, involving agrammatic subjects or not, must be evaluated in the normal ways and weighed against other data.

An illustrative example is in order. The tree-pruning hypothesis makes a specific claim that agrammatic data act as a constraint on linguistic theory. It is argued that Pollock's (1989) ordering of functional nodes, with TP above AgrP, should be preferred to other accounts since because the agrammatic data favor this ordering. No mention is made of the arguments and evidence that have led linguists since Pollock to posit AgrP above TP, but even with the agrammatic evidence alone there are reasons to be cautious. First, it is not the case that subjects always make tense errors and never agreement errors. Rather, there is a statistically significant dissociation. In a verb completion test, Hebrew subjects made 41% errors on tense and 4% errors on agreement (Friedmann, 2001). However, as has been pointed out, this means that despite the supposed pruning of tense, "it is available more often than not" (Edwards and Lightfoot, 2000: 32). In a sentence completion task, Benedet *et al.* (1998) found very different percentages: 85% errors on tense and 58% errors on agreement among English-speaking agrammatics. In this case, even though agreement is supposedly intact, it is available **less** often than not. And Penke (2000) describes data from German, Italian, French, and Dutch that she interprets as being inconsistent with the tree-pruning hypothesis. In Korean, too, there are anomalous data. On the face of it, the agrammatic data do not seem consistent or clear enough to warrant an adoption of Pollock's hierarchy. In any case, however clear the agrammatic data may or may not be, they must be weighed against the linguistic evidence before it is possible to appraise their potential contribution.

However, it should not escape our attention that, in this case, the data are actually organized in syntactic terms and that this at least means that it is **possible** to assess the value of the data to linguistic theory.

Conclusion

In principle, the idea that the study of agrammatism might contribute to theories of brain and of language is an appealing one. In practice, perhaps unsurprisingly given current preliminary levels of understanding, it turns out to be very hard to make very precise contributions.

The study of agrammatism to map out cerebral localization of specific language function is best seen as complementary to imaging research. Lesions in agrammatic subjects tend to be too large to permit precise characterizations of the relation between location and aspects of language, but if careful attention is paid to the extent of the lesions and if this is informative about differences in performance patterns, as has been shown in studies by, for example, Baum *et al.* (1990) and Blumstein *et al.* (1994), then progress is possible. In combination with imaging studies, if these are more consistently motivated by linguistic theory than has typically been the case, an increased understanding of the spatial organization of language may emerge.

The study of agrammatism to find out more about temporal aspects of cortical language processing is also an area of inquiry that holds out considerable promise. On-line methods with agrammatics coupled with EEG/MEG studies of normal subjects are likely to be particularly useful.

Finally, although the two bodies of knowledge that are of interest in neurolinguistics (including agrammatism) are brain theory and linguistic theory, it is evident that the relationship between linguistic theory and language processing will need to be clarified if more rapid progress is to be made. After all, any task that agrammatic subjects or normal subjects in neuroimaging or electrophysiological studies can complete must be a performance task involving some sort of processing, and linguistic theory has traditionally been agnostic with regard to such processing. If it can be shown that the grammar and the parser are one and the same thing, as some have proposed, then it will make the whole neurolinguistic enterprise immeasurably more tractable. For an intriguing effort in this direction, see Phillips (2004), whose proposal is not just programmatic but is supported by a growing set of empirical data. Processing issues in agrammatism, clearly critical to the neurolinguistic enterprise, are addressed in **Agrammatism I: Process Approaches.**

Agrell, Sigurd (1881–1937)

B Sigurd, Lund, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Per Sigurd Agrell, slavist, runologue, and poet, was born on January 16, 1881 and died on April 19, 1937. He became licentiat in Slavic languages in 1907 and received his Ph.D. in 1908. He was appointed lecturer at Lund University in 1909 (after some academic fighting), and was given the new chair in Slavic languages at Lund in 1921. He was known for his unconventional lifestyle, humor, and ready wit, which was admired by many students and friends. As a linguist, he was very creative and took on fundamental linguistic problems in new ways, which made him famous but also drew criticism.

Agrell's Ph.D. thesis (1908) dealt with Polish verbs, to which he applied the concepts of *Aspekt* and *Aktionsart*. Another difficult problem that Agrell treated is the varying stress in Russian verbs (1917).

Agrell moved in the literary circles of Sweden and wrote several poems, mostly sonnets. He published six collections of poems and translated works from French (Beaudelaire) and Russian (Tolstoy and Bunin).

In his later years, Agrell focused his mind on the runic alphabet, its use and origin, as in *Zur Frage nach dem Ursprung der Runennamen* (1928). He suggested that the runes were first used for magic purposes and assumed that the runes were associated with numbers, as were the letters of other alphabets at the time dominated by the Mithra mystery religion; see *Runornas talmystik och dess antika förebild* (1927) and *Senantik mysteriereligion och nordisk runmagi* (1931). His publications in this field inspired much discussion. Agrell suggested that the names of the runes had to do with their place numbers and assumed that the original name of the runic alphabet was *uthark* (not *futhark*). The runic alphabet would then begin with the Germanic name for ox (*urr*) like the Phoenician and Greek alphabets begin with *alpha*. The names of the second and third runes were interpreted accordingly. Agrell even associated the runes with the magical activities of the Lapps as published in a work on Lapp drums and Lapp magic (1934). He devoted much work to prove these theories and speculations, and they will always be associated with his name.

Aikhenvald, Alexandra (b. 1957)

B Narasimhan, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Alexandra (Sasha) Aikhenvald was born in Moscow, Russia on September 1, 1957. She was educated at the Department of Structural and Applied Linguistics, Philological Faculty, Moscow State University, where she received her B.A. in Linguistics in 1978. She began her graduate studies in Balto-Finnic languages before switching over to Hittite and the Anatolian family of languages for her master's degree, which she received in 1979 for her work on relative clauses in Anatolian languages. She earned her doctorate in 1984 from the Institute of Oriental Studies of the Academy of Sciences of the USSR in Moscow for dissertation research on the structural and typological classification of Berber languages. She then went on to work in the Middle East section of the Department of Languages in the Institute of Oriental Studies before moving to Brazil in 1989. While in Russia, she was a member of a team working on comparative grammars of Afroasiatic languages under the stimulating leadership of Igor M. Diakonoff. In Brazil, she took up the post of visiting Professor at the Universidade Federal de Santa Catarina, eventually reaching the rank of Full Professor with tenure in 1992. She remained in Brazil until 1994, during which time she also took up visiting positions at the State University of Campinas, Brazil, in 1992, and the Australian National University in 1993. In 1994, Aikhenvald moved to Australia, where she was appointed ARC Senior Research Fellow and Associate Director of the Research Centre for Linguistic Typology at the Australian National University. She is currently Professor of Linguistics and Associate Director of the Research Centre for Linguistic Typology at La Trobe University. In addition, she has served as Institute Professor at the Australian Linguistic Institutes in 1996 and 2002, and at the Linguistic Institute of the Linguistic Society of America in 2001.

Aikhenvald is most widely known for her work on aspects of (endangered) languages of the Arawak family from northern Amazonia, and has published grammars of Baré, Warekena (Guarequena), and Tariana (from northwest Amazonia). Her efforts to document languages that are on the verge of becoming extinct is motivated not only by a strong desire to preserve the cultural identity of a people but also by a belief in the role of linguistic diversity in providing crucial insights into the workings of the human mind. Her research focuses on making inductive generalizations about the categories in human language on the basis of exhaustive, crosslinguistic data and examining the role of linguistic categories in human cognition. Using extensive data from a range of typologically diverse languages, she has published substantial monographs on noun classification devices and on evidentiality, the linguistic marking of information source. In collaboration with R. M. W. Dixon, she has also edited a number of volumes that take a linguistic typological perspective on topics such as transitivity, adjectives, and the notion of 'word.'

Aikhenvald's wide-ranging research interests additionally span the fields of sociolinguistics, historical linguistics, and language maintenance and decay. She has investigated issues of areal diffusion and genetic inheritance to account for the grouping of North Arawak languages in the Amazon basin. Aikhenvald's scholarly contributions also include a monograph based on detailed fieldwork-based investigation of language contact in Amazonia, in which she explores the mechanisms of language contact and change in two languages from genetically and typologically unrelated families (North Arawak and Tucano). Using oral histories and primary observations of language use among the Tariana people of Santa Rosa and Periquitos, Aikhenvald considers the impact of language contact between East Tucanoan languages and Tariana at a number of levels including phonology, morphology, syntax, and discourse, as well as the diglossic relation between Portuguese and Tariana.

Aikhenvald's extensive fieldwork experience includes work in Tashelhit, Kabyle, and Tamachek (Berber languages), Baniwa, Warekena, Baré, Tariana (Arawak family), Paumarí (Arawá family), and Ngala and Manambu (Ndu family, New Guinea, Papuan). In addition to work in Berber and the Amazonian languages, Aikhenvald has also published a grammar of Modern Hebrew and has a grammar of Biblical Hebrew (Hebrew, Ancient) in press (in Russian). She has worked on a number of translations, including Katona József's *Bank Ban* from Hungarian into Russian (with a poet, Yuri A. Aikhenvald), Hungarian poetry into Russian, and Lucacs's philosophical works from German into Russian. She is a polyglot, with fluency in a range of languages including English, Russian, Portuguese, French, German, Manambu, Tariana, and Estonian and also has a reading knowledge of Hebrew, Latin, Italian, Spanish, Eastern Yiddish, Hungarian, Finnish, Lithuanian, and Tucano. For her contributions to the field of linguistics, Aikhenvald has been honored with a number of awards, including the first prize in national competitions for publications on Oriental languages

in 1988 and 1990, and the Centenary medal for service to Australian society and the humanities in linguistics and philology in 2003.

Ainu

M Shibatani, Rice University, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Ainu is a near-extinct language that was once spoken widely in the northern part of the main Japanese island of Honshu as well as the Hokkaido island, in Sakhalin, and in the Kurile Islands. The current Ainu population, concentrated mainly in Hokkaido, is estimated to be around 24 000, but as a result of intermarriage between Ainu and Japanese, pure-blood Ainu are said to number less than 1% of that figure. Ainu is no longer used as a means of daily communication, and is remembered to a varying extent only by a handful of people of advanced age.

Ainu has not developed a writing system, but it is endowed with a rich tradition of oral literature. In addition to various kinds of songs, e.g., love songs and boating songs, Ainu oral literature contains both verse and prose. The verse forms, generally called *yukar* in Ainu, are recited epics that relate to the experiences of gods or to the experiences of love and war of heroes. The language of *yukar* differs significantly from the spoken language; it is more conservative and has less dialectal variation as compared with the colloquial language. The two types of language show differences in both syntax and vocabulary, although there is a great deal of overlap. The most salient difference between the two is that the language of *yukar* tends to be more strongly polysynthetic than its colloquial counterpart. The language of *yukar* will be referred to as Classical Ainu, but the difference between this type of language and the colloquial form is more a difference in genre than in chronology.

in 1988 and 1990, and the Centenary medal for service to Australian society and the humanities in linguistics and philology in 2003.

Ainu

M Shibatani, Rice University, Houston, TX, USA

Ainu is a near-extinct language that was once spoken widely in the northern part of the main Japanese island of Honshu as well as the Hokkaido island, in Sakhalin, and in the Kurile Islands. The current Ainu population, concentrated mainly in Hokkaido, is estimated to be around 24 000, but as a result of intermarriage between Ainu and Japanese, pure-blood Ainu are said to number less than 1% of that figure. Ainu is no longer used as a means of daily communication, and is remembered to a varying extent only by a handful of people of advanced age.

Ainu has not developed a writing system, but it is endowed with a rich tradition of oral literature. In addition to various kinds of songs, e.g., love songs and boating songs, Ainu oral literature contains both verse and prose. The verse forms, generally called *yukar* in Ainu, are recited epics that relate to the experiences of gods or to the experiences of love and war of heroes. The language of *yukar* differs significantly from the spoken language; it is more conservative and has less dialectal variation as compared with the colloquial language. The two types of language show differences in both syntax and vocabulary, although there is a great deal of overlap. The most salient difference between the two is that the language of *yukar* tends to be more strongly polysynthetic than its colloquial counterpart. The language of *yukar* will be referred to as Classical Ainu, but the difference between this type of language and the colloquial form is more a difference in genre than in chronology.

In terms of genetic affiliation, Ainu is best considered as a language isolate. Although there have been suggestions that Ainu is related to such language families as Paleo–Asiatic, Ural–Altaic, Indo–European, and Malayo–Polynesia or to individual languages such as Gilyak and Eskimo, none of these suggestions has progressed beyond the level of speculation. Hypotheses relating Ainu to Japanese have also been entertained by many scholars, but other than the similarities due to lexical borrowing and typological characteristics rooted in the shared basic word order (Subject–Object–Verb), no strong evidence has been uncovered to relate the two languages. Indeed, Ainu has a number of morphological characteristics that distinguish it from Japanese, e.g., extensive use of personal affixes and a polysynthetic character as well as absence of verbal inflections.

Ainu has a rather simple phonological system, with five vowel phonemes (/i, e, a, o, u/) and 12 consonantal phonemes (/p, w, m, t, s, c, y, n, r, k, ʔ, h/). Syllable-initial vowels are preceded by a glottal stop, e.g., *aynu* [ʔajnu] 'person,' and this fact makes Ainu syllables conform to one of the following types: CV, CVC (for Hokkaido Ainu) or CV, CVV (long vowel), CVC (for Sakhalin Ainu).

According to the pitch accent system of the language, Ainu syllables are pronounced with either high or low pitch. In words consisting of stems and affixes, the stems have high pitch, e.g., *nú-pa* 'to hear-pl.OBJ.' In other two- and three-syllable words, high pitch falls on the first syllable if it is a heavy syllable, i.e., a diphthong or a closed syllable, e.g., *áynu* 'person.' In all other words, high pitch occurs in the second syllable, e.g., *kirá* 'to flee.'

Among the small number of phonological processes, the most notable are assimilatory and dissimilatory processes of the following type: *akor nispa* → *akon nispa* 'our chief,' *pon-pe* → *pompe* 'small thing,' (assimilation); *kukor rusuy* → *kukon rusuy* 'want to have' (dissimilation).

Both nominal and verbal morphologies are characterized by extensive use of affixes. In nominal morphology perhaps the most notable are deverbal nominal suffixes that derive nominal expressions from verbs. The suffix *-p(e)* derives a noun that denotes a person or things characterized by the meaning of the original verb, e.g., *pirka* 'good' → *pirka-p* 'good thing,' *wen* 'bad' → *wen-pe* 'poor man.'

Two other noun-forming derivational affixes are the suffixes *-i* and *-ike*. The former yields nouns having the meaning 'X-place' or 'X-time,' and the latter produces nouns with the meaning 'thing' or 'person,' e.g., *esan* 'go out there' → *esan-i* 'place that is protruded, i.e., peninsula,' *poro* 'big' → *poro-ike* 'bigness, big thing/person.'

One notable feature of these suffixes with theoretical significance is that they, especially *-p(e)* and *-i*, also attach to phrases and clauses, functioning as both lexical and phrasal nominalizing suffixes, e.g., *a-koyki rok-pe* (1sg-strike PERF-SUF) 'the one I have fought,' *a-yanene-p ya-kotan-oro esina-p* (1sg-dislike-SUF REFL-village-from hide-SUF) 'what I dislike is hiding one's village (from which one came).'

Possession is expressed by the use of personal affixes that, when attached to verbs, index the subject of transitive clauses, e.g., *a-maci* (1sg-wife), *e-maci* (2sg-wife) 'young wife,' *maci* 'his wife.'

In both Classical and colloquial Ainu, intransitive and transitive verbs each have distinct sets of personal affixes indicating person and number of the subject and object, e.g., Classical Ainu intransitive affixes: *itak-an* (speak–1sg) 'I speak,' *e-itak* (2sg-speak) 'you (sg) speak,' *itak* 'he/she speaks'; Classical Ainu transitive affixes: *a-kor* (1sg-have) 'I have,' *e-kor* (2sg-have) 'you (sg) have,' *kor* 'he/she has.' These subject-indexing affixes combine with object-indexing affixes, yielding forms such as *a-e-kore* (1sg–2sg-give) 'I give you,' *e-i-kore* (2sg–1sg-give) 'you give me.'

Ainu verbs – Ainu makes no distinction between verbs and adjectives – also index the plurality of the subject and object. The plural verb forms typically co-occur with a plural subject when the verb is intransitive and with a plural object when it is transitive. However, Ainu also shows cases of plural verbs co-occurring with plural transitive subjects. Plural verbs are of either suppletive type (*arpa* 'go,' *paye* 'go.pl') or productive-suffixed type (*kor* 'have (sg)': *kor-pa* 'have (pl)'); e.g., *An-an* (be-1sg) 'I was (there)': *Oka-an* (be.pl-1pl) 'We were (there)'; *Icen poronno kor-pa* (money lot have-pl) 'They had a lot of money' (Ishikari dialect); *Sisam sokor goza sinep hok-pa wa arki* (Japanese from mat one buy-pl and come.pl) 'They bought one mat from a Japanese and came' (Ishikari dialect).

Plural verb forms are also used as honorifics, e.g., *Kane rakko a-res-pa kamuy ronnu* (golden otter 1pl-raise-pl god kill.pl) 'Our honorable god, whom we have raised, killed the golden sea otter'.

The most notable feature of Ainu verbal morphology is incorporation of various elements – the feature that contributes to the polysynthetic character of Ainu, especially Classical Ainu. Nouns corresponding to intransitive subjects and those corresponding to transitive objects are incorporated, though many instances of the former type appear to be frozen expressions, e.g., *Sir-pirka* (weather-good) 'It's fine.' Typical noun incorporation is of the following type, where incorporation of a noun corresponding to an object results in an intransitive expression with

concomitant change in the personal affix: *Cise ci-kar* (house 1pl-make) 'We make a house': *Cise-kar-as* (house-make-1pl) 'We make a house' (Ishikari dialect).

In addition, Ainu verbs incorporate adverbs, e.g., *Toyko a-kikkik* (thoroughly 1sg-beat) 'I beat (him) up thoroughly': *A-toyko-kikkik* (1sg-thoroughly-beat). While no more than one noun can be incorporated into the verb at a time, a noun and an adverb can be incorporated into one verb base at the same time, e.g., *Pinne kamuy kiraw-rik-kur-roski* (male god horn-high-EXPL-raise) 'The male (dragon) god raised the horns high.'

Moreover, Ainu verbal morphology permits applicative extension, thereby exhibiting the following paraphrases between postpositional expressions and the corresponding applicative expressions: *Poro cise ta horari* (big house at live) 'He lives in a big house': *Poro cise e-horari* (big house APPL-live) 'He lives in a big house'; *kaya ari terke* (sail with run) 'run by a sail': *kaya e-terke* (sail APPL-run) 'run by a sail.'

A combination of noun incorporation and applicative extension yields an expression such as *Nea cep a-pone-ko-kuykuy* (that fish 1sg-bone-APPL-bite) 'I bit that fish with its bone.'

Ainu syntax is consistently head-final, thereby exhibiting word order patterns similar to those observed in other head-final languages such as Japanese and Korean. Thus, the basic word order is SOV: *Kamuy aynu rayke* (bear person kill) 'The bear killed the man.' Postpositions are used rather than prepositions: *cise ta* (home at) 'at home,' and modifiers precede the heads they modify: *pirka kewtum* (good heard) 'good heart,' [*beko respa*] *sisam* ([cow raise] Japanese) 'a Japanese who raises cows,' *sapo ninkarihi* (sister earrings) 'sister's earrings,' *toan seta* (that dog) 'that dog,' *sine aynu* (one person) 'one person,' *turasno paye* (quickly go) 'go quickly,' *a-e rusuy* (1sg-eat want) 'want to eat,' *menoko kasuno okirasunu* (woman than strong) 'stronger than a woman.'

Subordinating conjunctions occur after subordinate clauses, which come before main clauses, e.g., *E-eh kusu anekiroro-an* (2sg-came because happy-1sg) 'Because you came, I am happy' (Sakhalin dialect).

Auxiliary verbs are not generally marked by personal affixes, which are attached to the main verbs. And finally, question sentences are marked by the final particle *ya*, or are simply indicated by rising intonation alone. Like many other head-final languages, interrogative pronouns need not move to sentence-initial position. The following final example illustrates the use of auxiliary verbs and interrogative sentence pattern: *Eani hemanta e-e rusuy ya* (you what 2sg-eat want Q) 'What do you want to eat?'

Kazimierz Ajdukiewicz, Polish logician and philosopher, was born at Tarnapol and educated at Cracow and Lvov. He studied philosophy under Twardowski and logic under Lukasiewicz. After the war Ajdukiewicz became one of the leading members of the Lvov–Warsaw school. Other members of this school were Twardowski, Łukasiewicz, Leśniewski, Kotarbiński and Tarski. From 1928 until 1952, Ajdukiewicz taught logic and philosophy at the universities of Warsaw, Lvov and Poznan. Until his death he was the chief editor of Studia Logica.

Ajdukiewicz devoted a great deal of his time and energy to the study of the relationship between language and knowledge. According to him the theory of knowledge is the science of cognitive acts and results. Cognitive acts are inseparably connected with language and he identified their products with the meaning of sentences. It was as a part of his theory of knowledge that Ajdukiewicz developed a theory of language.

Ajdukiewicz thought that to speak a language L is to have the disposition to accept all and only the sentences that the speakers of L accept. In his study of language he tried to describe the kind of rules that

concomitant change in the personal affix: *Cise ci-kar* (house 1pl-make) 'We make a house': *Cise-kar-as* (house-make-1pl) 'We make a house' (Ishikari dialect).

In addition, Ainu verbs incorporate adverbs, e.g., *Toyko a-kikkik* (thoroughly 1sg-beat) 'I beat (him) up thoroughly': *A-toyko-kikkik* (1sg-thoroughly-beat). While no more than one noun can be incorporated into the verb at a time, a noun and an adverb can be incorporated into one verb base at the same time, e.g., *Pinne kamuy kiraw-rik-kur-roski* (male god horn-high-EXPL-raise) 'The male (dragon) god raised the horns high.'

Moreover, Ainu verbal morphology permits applicative extension, thereby exhibiting the following paraphrases between postpositional expressions and the corresponding applicative expressions: *Poro cise ta horari* (big house at live) 'He lives in a big house': *Poro cise e-horari* (big house APPL-live) 'He lives in a big house'; *kaya ari terke* (sail with run) 'run by a sail': *kaya e-terke* (sail APPL-run) 'run by a sail.'

A combination of noun incorporation and applicative extension yields an expression such as *Nea cep a-pone-ko-kuykuy* (that fish 1sg-bone-APPL-bite) 'I bit that fish with its bone.'

Ainu syntax is consistently head-final, thereby exhibiting word order patterns similar to those observed in other head-final languages such as Japanese and Korean. Thus, the basic word order is SOV: *Kamuy aynu rayke* (bear person kill) 'The bear killed the man.' Ajdukiewicz, Kazimierz (1890–1963)

V Sánchez

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 1, pp. 62–63, © 1994, Elsevier Ltd.

Kazimierz Ajdukiewicz, Polish logician and philosopher, was born at Tarnapol and educated at Cracow and Lvov. He studied philosophy under Twardowski and logic under Lukasiewicz. After the war Ajdukiewicz became one of the leading members of the Lvov–Warsaw school. Other members of this school were Twardowski, Łukasiewicz, Leśniewski, Kotarbiński and Tarski. From 1928 until 1952, Ajdukiewicz taught logic and philosophy at the universities of Warsaw, Lvov and Poznan. Until his death he was the chief editor of Studia Logica.

Ajdukiewicz devoted a great deal of his time and energy to the study of the relationship between language and knowledge. According to him the theory of knowledge is the science of cognitive acts and results. Cognitive acts are inseparably connected with language and he identified their products with the meaning of sentences. It was as a part of his theory of knowledge that Ajdukiewicz developed a theory of language.

Ajdukiewicz thought that to speak a language L is to have the disposition to accept all and only the sentences that the speakers of L accept. In his study of language he tried to describe the kind of rules that

govern the acceptance of sentences of L. Among these rules he distinguished three kinds: axiomatic, deductive, and empirical rules. The axiomatic rules demand the unconditional acceptance of certain sentences. For example, the following sentences should be accepted without having recourse to experience: 'Every man is a man'; 'Every square has four sides.' A person who rejects the sentence 'Every man is a man' or 'Every square has four sides' shows that he does not understand the meaning of these sentences in the way speakers of English do. The deductive rules, on the other hand, require the conditional acceptance of sentences. If one sentence is accepted, then the deductive rules dictate that another sentence must also be accepted. Who accepts the sentences 'If today is Sunday then tomorrow is Monday' and 'Today is Sunday' must also accept 'Tomorrow is Monday.' If a person accepted both 'If today is Sunday then tomorrow is Monday' and 'Today is Sunday' but rejected 'Tomorrow is Monday,' this behavior would show that he understands those sentences in an idiosyncratic way. Finally, the empirical rules demand that certain sentences have to be accepted in the face of certain experience, for example the sentence 'It hurts' should be accepted when one is in pain.

It was one of Ajdukiewicz's most cherished beliefs that 'since the languages studied by logicians are in many respects modeled on natural languages, it seems that logicians may be able to make some contribution to general linguistics.' Inspired by the treatment of formal languages common among Hilbert and his disciples, Ajdukiewicz noticed that a deductive system can be characterized, first by the rules that select the set of its well-formed expressions, secondly, by the rules that select certain expressions as axioms and, finally, by the rules that determine a logical consequence relation.

Above what has been described is the role played by the last two rules in the mechanism of sentence acceptance. However, Ajdukiewicz's most celebrated contribution to the study of language is related to the first feature of deductive systems: the rules that select the class of well-formed expressions. On the basis of certain ideas of Leśniewski and Husserl, Ajdukiewicz developed a categorial grammar that specifies which combinations of expressions are admissible as well-formed expressions of a given language. This grammar is used to distinguish loose strings of expressions from connected strings.

Ajdukiewicz's categorial grammar is a language recognition device that works as follows. We have at our disposal primitive categories and a category functor, '/'. Complex categories are built from two basic categories n (proper names) and s (sentences) and a recursive procedure: If β and α are categories, then so is (β/α).

The recognition work starts with assigning each word to a category. To determine the category of a complex expression we write first the categories of its elements. After this, we read the string of categories from left to right. When the first substring of the form $(\beta/\alpha)\ \alpha$ we replace this substring by β. This yields a new string of categories. The new string can then be rescanned, applying the reduction rule wherever possible. The complex expression belongs to the category γ only if successive applications of the procedure finally lead to the string γ.

Ajdukiewicz's original formulation of categorial grammar was mainly focused on the formal languages of logic. To give an example of his recognition mechanism applied to such a language, consider the categorial analysis of the language of oral logic (in note form). The following initial categorization can be taken as a starting point:

a. Propositional letters belong to the category s.
b. Unary connectives belong to the category s/s.
c. Binary connectives belong to the category (s/s) /s. Then it is dictated that
d. A string Σ belongs to the set of well-formed expressions if the successive applications of the reduction procedure ends in s.

Consider now the string $\wedge\ p\ \neg\ \vee\ qr$ (in infix notation: $(p \wedge \neg (q \vee r))$). This string is a well-formed Polish formula since the reduction procedure reduces the categories of their elements to s, as appears from the reduction tree shown below:

$\wedge$	p	$\neg$	$\vee$	q	r	
(s/s)/s	s	s/s	(s/s)/s	s	s	initial categorization
(s/s)/s	s	s/s	s/s		s	result first scanning
(s/s)/s	s	s/s	s			result second scanning
(s/s)/s	s	s				result third scanning
s/s						result fourth scanning
s						result fifth scanning

Ajdukiewicz's categorial grammar is a language recognition device driven by semantics. This is illustrated by his discussion of the proper categorization of the quantifier symbols of predicate logic. He contemplates the possibility of assigning the quantifiers to the category s/s, but rejects this on semantic grounds: this assignment is semantically inadequate as there are only four functions available that map truth-values onto truth-values, none of these providing an adequate semantics for the quantifiers. (The correct category for the (Russellian) quantifiers is s/ (s/n): they are second-order unary predicates over sets.)

Although Ajdukiewicz's main interest was devoted to logical languages, categorial grammar has proved to be a fruitful mechanism for the study of natural languages as well. In Ajdukiewicz's view, certain words in

natural languages may be regarded as functors which, when combined with one term, form a sentence. Words with this property are called 'one-term (or: unary) sentence-forming functors.' Intransitive verbs, for example, belong to this category. So does the negation operator, since it forms a (new) sentence when combined with a (sentential) term. Then there are two-term (binary) sentence-forming functors, such as transitive verbs (*build, push, lift*, etc.). Here, too, truth-functional operators such as 'and' or 'or' count as two-term sentence-forming functors, since they take two (sentential) terms to form a (new) sentence. The expressions to which a functor applies are called its arguments. Given the expression 'Abélard wanders,' it can be said that 'wanders' is its functor and 'Abélard' its argument.

According to Tarski the resulting categorial grammar, when applied to natural language, is the grammatical counterpart of the logical theory of types developed by Russell. Bar-Hillel (1953), Lambek (1958), and Geach (1962) developed categorial grammar further as a natural language recognition device. Their efforts culminated in the construction of categorial grammars that are more flexible than Ajdukiewicz's original version. The intimate relationship between categorial grammars and natural language established in Thomason (1974) is the topic of many of the articles collected in Buszkowski *et al*. (1988), and Oehrle *et al*. (1988). Van Benthem (1991) contains a systematic discussion of several logical aspects of categorial grammars that were already adumbrated in Tarski's remark about categorial grammar and the theory of types.

Akan

M E Kropp Dakubu, University of Ghana, Legon, Accra, Ghana

© 2006 Elsevier Ltd. All rights reserved.

The Akan language is spoken throughout the central portion of Ghana. It is the most widely spoken member of a family of about 20 languages known as Tano or Volta-Comoe spoken in Ghana and the eastern Ivory Coast. Formerly the entire group was referred to as Akan. These languages belong to the Niger-Congo family. Within Niger-Congo they are part of the Kwa grouping.

Dialects and Their Distribution

The name 'Akan' is not generally used by speakers of the language, who refer to their language as Fante, Twi, or Brong. These Akan speech forms constitute a dialect continuum running from north to south in Ghana. 'Fante' refers to the dialects spoken in those regions that reach the sea, in the Central Region and parts of the Western Region of Ghana. 'Twi' is the most general term, referring to a wide range of dialects, of which the best known are Akuapem, the main tongue of the Eastern Region, and Asante, the dialect of the Ashanti Region. Others are Akyem and Kwahu. In genetic terms, Akuapem is more closely related to Fante than to the other dialects, but all of these dialects are mutually intelligible. The Brong dialect group of the Brong-Ahafo Region to the north of Ashanti is mutually intelligible with Asante Twi, but there is less mutual intelligibility with the dialects spoken farthest south.

natural languages may be regarded as functors which, when combined with one term, form a sentence. Words with this property are called 'one-term (or: unary) sentence-forming functors.' Intransitive verbs, for example, belong to this category. So does the negation operator, since it forms a (new) sentence when combined with a (sentential) term. Then there are two-term (binary) sentence-forming functors, such as transitive verbs (*build, push, lift*, etc.). Here, too, truth-functional operators such as 'and' or 'or' count as two-term sentence-forming functors, since they take two (sentential) terms to form a (new) sentence. The expressions to which a functor applies are called its arguments. Given the expression 'Abélard wanders,' it can be said that 'wanders' is its functor and 'Abélard' its argument.

According to Tarski the resulting categorial grammar, when applied to natural language, is the grammatical counterpart of the logical theory of types developed by Russell. Bar-Hillel (1953), Lambek (1958), and Geach (1962) developed categorial grammar further as a natural language recognition device. Their efforts culminated in the construction of categorial grammars that are more flexible than Ajdukiewicz's original version. The intimate relationship between categorial grammars and natural language established in Thomason (1974) is the topic of many of the articles collected in Buszkowski *et al*. (1988), and Oehrle *et al*. (1988). Van Benthem (1991) contains a systematic discussion of several logical aspects of categorial grammars that were already adumbrated in Tarski's remark about categorial grammar and the theory of types.

The Akan language is spoken throughout the central portion of Ghana. It is the most widely spoken member of a family of about 20 languages known as Tano or Volta-Comoe spoken in Ghana and the eastern Ivory Coast. Formerly the entire group was referred to as Akan. These languages belong to the Niger-Congo family. Within Niger-Congo they are part of the Kwa grouping.

Dialects and Their Distribution

The name 'Akan' is not generally used by speakers of the language, who refer to their language as Fante, Twi, or Brong. These Akan speech forms constitute a dialect continuum running from north to south in Ghana. 'Fante' refers to the dialects spoken in those regions that reach the sea, in the Central Region and parts of the Western Region of Ghana. 'Twi' is the most general term, referring to a wide range of dialects, of which the best known are Akuapem, the main tongue of the Eastern Region, and Asante, the dialect of the Ashanti Region. Others are Akyem and Kwahu. In genetic terms, Akuapem is more closely related to Fante than to the other dialects, but all of these dialects are mutually intelligible. The Brong dialect group of the Brong-Ahafo Region to the north of Ashanti is mutually intelligible with Asante Twi, but there is less mutual intelligibility with the dialects spoken farthest south.

History and Development

Lists of several hundred words in Fante were published in Europe during the 17th and 18th centuries, but the language became a written language with a printed literature in the first half of the 19th century. The first written form was based on the Akuapem dialect, and was the work of members of the Basel Mission, which became established in the Eastern Region in the 1830s. The major names connected with this work are H. N. Riis, who published the first grammar in German in 1853 and in English in 1854, and Johann Gottlieb Christaller, whose grammar and dictionary appeared in 1875 and 1881, respectively. His collection of 3,600 Akan proverbs appeared in 1879. Christaller's work was important not only for Akan but for West African linguistics generally, because he analyzed the characteristic vowel harmony system and the tone system (see later), and their significance for the grammar.

The Akuapem-based orthography was used in schools of the Basel Mission, and later throughout the Twi-speaking areas until an Asante orthography was established in the 1950s. Since then, three orthographies, Fante, Asante, and Akuapem, have been used in the schools. A Unified Akan Orthography was developed in 1978 and published, but has not been put into practice by publishers or teachers. Nevertheless, more works have been published in Akan than in any other Ghanaian language, more than half of them in the Akuapem orthography.

Sociolinguistic Situation

As mother tongue of about 43% of the population of Ghana (7 550 405 out of about 18 million) and spoken as a second language by many more, Akan is indisputably the most commonly spoken Ghanaian language. Asante, with 2 578 829 speakers, is the largest dialect, Fante coming second with 1 723 573 speakers (figures are based on the report of the 2000 Census). Exactly how many speak Akan as a second language is not known, but there are very few places in Ghana where a speaker cannot be found. The Asante dialect seems to be the most widely known, and is expanding. Although Accra, the capital of Ghana, historically is not an Akan town, there are strong indications that today Akan is more widely spoken there than any other Ghanaian language.

From the 17th century until British conquest in the 20th century, Akan was the language of expanding kingdoms, of which the Ashanti became the largest and most famous. The resulting impact on the other languages of Ghana was considerable, especially in the south. Virtually all southern Ghanaian languages have borrowed Akan words related to war, government/state, the arts (especially music), and personal names and appellations. Akan is the source of several English words and proper names, especially in the Caribbean. The most well-known English word of Akan origin is probably the name of the Jamaican folktale character, Anancy, from Akan *ananse* 'spider'. Another is okra, from Akan *ŋ-koro-ma*.

Akan is the language most used after English in the electronic public media, and in some areas is used more than English. This is most noticeable on the FM radio stations distributed throughout Akan-speaking regions and in Accra. It is fairly often heard on television and is very commonly used in both television and radio advertising. However, there is little if any print journalism in Akan, although there has been more in the past.

Akan is a school subject in Akan-speaking regions, in many Accra schools, and in teacher training colleges. It can be studied to degree level at the University of Ghana and the University of Cape Coast, and is an area of specialization at the University College of Education at Winneba.

Aspects of the Ethnography of Speaking

Formal speech is very important in Akan culture. Every chief or king has an *ɔkyeame*, or spokesman, whose function is to speak for the chief on all formal occasions. This man is highly regarded as a master of the language. Elegant speech, especially that used at court, is profuse and indirect. Mastery of proverbs and their appropriate use are important aspects of this style.

Major Linguistic Features

The Sounds of Akan

This section is based mainly on Dolphyne's (1988) *The Akan (Twi-Fante) language*, which should be consulted for more detail.

Consonants The Akan consonants p, b, t, d, k, g, m, n, f, s, h, w, l, r, and y are usually pronounced much as they are in English, although n is pronounced [ŋ] in some contexts, e.g., in *nkwan* 'soup'. The spellings ky, gy, and hy, however, are pronounced similarly to English ch, j, and sh, respectively. Akan also has rounded consonants with no comparable English sounds, because the inner parts of the lips are rounded and the sound is also palatalized. These sounds include tw [tɕɥ], dw [dʑɥ], and hw [ɕɥ]. The syllabic

nasals *m n* (representing both [n] and [ŋ]) always have the same position of articulation as the following consonant, thus *mpaboa* 'shoes' but *nsuo* 'water'.

The most obvious difference between Fante and the other dialects is that in Fante, t and d are pronounced [ts] and [dz] before front vowels. Thus Fante has *dzi*, meaning 'eat', whereas other dialects have *di*, and *itsir* 'head', whereas other dialects have *etire* (or *eti*). Also before front vowels, n in Fante is pronounced as ny; for example, *nye* 'and' is *ne* in other dialects. The sound [l] occurs mainly in loanwords from English, although it exists in both Asante and Fante dialects as an alternative pronunciation for [r] or [d] in some words.

Vowels and Vowel Harmony Akan has nine oral vowel phonemes, /i ɪ e ɛ u ʊ o ɔ a/, and five nasal vowels, /ĩ ɪ̃ ũ ʊ̃ ã/. The vowels [ɪ] and [ʊ] are spelled e and o, respectively. Asante and Akuapem have a tenth vowel, [ɑ]. These vowels pattern according to the rules of cross-height or advanced tongue root vowel harmony. This means that any of the vowels except [ɑ] can be the vowel of a stem syllable, but for prefixes and some suffixes the vowels fall into two sets. These are /a ɪ ɛ ʊ ɔ ĩ ʊ̃ ã/ and /ɑ i e u o ĩ ũ/. A prefix to a word must have a vowel from the same set as the stem vowel. Thus, for example, the pronoun prefix meaning 'he, she' is pronounced [o] in *odi* 'she eats', but [ɔ] in *ɔhwɛ* 'he looks at it', because the verb stem vowels /i/ and /ɛ/ belong to different sets.

The Fante dialects also have rounding harmony, whereby the prefix vowels are rounded if the stem vowel is. Thus, in Fante, the expression meaning 'I am going' is pronounced [mʊ-rʊ-kɔ], because the stem *kɔ* has a rounded vowel, but in other dialects it is pronounced [mɪ-rɪ-kɔ].

Tone Every syllable carries contrastive tone. There are two contrastive tone levels, high and low. In a sentence or phrase the pitch of high tones is lowered after a low tone, so that in a sentence such as *Pàpá Kòfí rèfré nè bá* 'Papa Kofi is calling his child', each high tone syllable is pronounced at a lower pitch than the earlier high tone syllables. Tone is not reflected in any of the Akan orthographies.

Word Formation

Nouns Most nouns consist of a stem with a singular or a plural prefix. The common singular prefixes are created using the vowels o, e, and a (varying according to the vowel harmony rules), and the common plural prefixes use the vowel a (only if there is a different vowel prefix in the singular) or a syllabic nasal. Thus we have *ɔ-hene* 'king', plural *a-hene*, and *ɔ-kwasea* 'fool', plural *n-kwasea*. Some nouns have no singular prefix, only a plural: thus *gyata* 'lion', plural *a-gyata*, and *kuku* 'pot', *n-kuku* 'pots'. Some adjectives also have singular and plural forms, but there is no noun class agreement of the Bantu type.

Nouns referring to persons often have a suffix *-ni* in the singular, which is replaced by *-fo* in the plural. Thus, *o-buro-ni* 'European person', in the plural is *a-buro-fo*. Kinship terms are usually formed with a suffix *-nom* with no change in the prefix, e.g., *ɛna* 'mother', *ɛna-nom* 'mothers'.

Verbs With slight variations among the dialects, the Akan verb is inflected principally for aspect: completive with a suffix with a form that depends on the final stem vowel, perfect with the prefix *á-*, progressive with the prefix *re-*, and habitual and stative forms that have no prefix or suffix and differ only in the tone of the verb. There is also a future marker *bé-*. The consecutive form has a prefix *a-* and is used only in serial verb constructions. The negative is expressed by a prefix consisting of a syllabic nasal before the verb stem, and the imperative also by a syllabic nasal prefix but with high tone.

Syntax

Word Order Akan has subject-verb-object word order. In a noun phrase, adjectives and determiners follow the noun but possessives precede it, as shown in the following examples:

Abofra	no	re-	n-	noa	bi
child	the	PROG-NEG-cook			some

'the child will not cook any'

Kwasi	kyɛ-ɛ	abofra	no	paanoo
Kwasi	give-COMPL	child	the	bread

'Kwasi gave the child bread'

Amma	sika
'Amma's	money'

Postpositions Locations are represented by a special class of nouns called postpositions at the end of the locative phrase. An example is *so* 'top, on', as in the following sentence:

Sekan	bi	da	ɔpon no so
knife	some	lie	table the on

'a knife is lying on the table'

There is only one preposition, wɔ 'at'.

Serial Constructions Serial verb constructions, in which two or more verbs and their objects occur in sequence with a single subject and no conjunctions to form a complex clause, are a characteristic feature of Akan syntax. For example:

Kwasi de	paanoo kyɛ-ɛ	abofra no
Kwasi took	bread give-COMPL	child the

'Kwasi gave bread to the child'

ɔ-bɛ-tɔ	nwoma no	a-	kan
she-FUT-buy	book	the	CONSEC-read

'she will buy the book and read it'

Akkadian

G Deutscher, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Akkadian is an extinct Semitic language spoken in ancient Mesopotamia, the 'land between the rivers' (Tigris and Euphrates), in an area that roughly corresponds to today's Iraq. In the later second millennium B.C., Akkadian was also a lingua franca throughout the Near East. Akkadian was written on clay tablets in the cuneiform script in a system that combined syllabic and logographic signs. It is one of the earliest and longest attested languages, with a history that starts around 2500 B.C. and spans more than two thousand years. The ancient name of the language, Akkadûm, derives from the city of Akkade, founded by King Sargon as his capital around 2300 B.C.

From the second millennium B.C., two distinct dialects of Akkadian emerged: Babylonian and Assyrian. Babylonian was spoken in the southern part of Mesopotamia, and Assyrian was spoken in the northern part. During the first millennium B.C., Aramaic gradually ousted Akkadian as the language of the region, and Akkadian ceased to be spoken sometime around 500 B.C. Some texts in Akkadian continued to be written even until the first century A.D., but the language then fell into oblivion, and was rediscovered only in the nineteenth century, when the cuneiform writing system was deciphered. Today, hundreds of thousands of Akkadian texts have been discovered, encompassing many different genres, including poetry (such as the epic of Gilgamesh), religious compositions, royal and monumental inscriptions, histories, monolingual and multilingual dictionaries (word-lists), grammatical texts, astronomical and mathematical texts, legal documents (such as the Code of Hammurabi), private and diplomatic correspondence, and an endless quantity of economic and administrative documents.

The history of the Akkadian language is conventionally divided into four main chronological periods: Old Akkadian (2500–2000 B.C.), Old Babylonian/Old Assyrian (2000–1500 B.C.), Middle Babylonian/Middle Assyrian (1500–1000 B.C.), and Neo-Babylonian/Neo-Assyrian (1000–500 B.C.). The conventional name 'Old Akkadian' for the earliest attested period is based on the (probably mistaken) assumption that no dialectal variation between the Babylonian and Assyrian idioms existed before the second millennium. The Old Babylonian dialect was considered the classical stage of the language by later generations of Babylonians and Assyrians, and it was the language towards which the later literary idiom (sometimes known as 'Standard Babylonian') aspired.

Kwasi de	paanoo kyɛ-ɛ	abofra no
Kwasi took	bread give-COMPL	child the

'Kwasi gave bread to the child'

ɔ-bɛ-tɔ	nwoma no	a-	kan

Akkadian

G Deutscher, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Akkadian is an extinct Semitic language spoken in ancient Mesopotamia, the 'land between the rivers' (Tigris and Euphrates), in an area that roughly corresponds to today's Iraq. In the later second millennium B.C., Akkadian was also a lingua franca throughout the Near East. Akkadian was written on clay tablets in the cuneiform script in a system that combined syllabic and logographic signs. It is one of the earliest and longest attested languages, with a history that starts around 2500 B.C. and spans more than two thousand years. The ancient name of the language, Akkadûm, derives from the city of Akkade, founded by King Sargon as his capital around 2300 B.C.

From the second millennium B.C., two distinct dialects of Akkadian emerged: Babylonian and Assyrian. Babylonian was spoken in the southern part of Mesopotamia, and Assyrian was spoken in the northern part. During the first millennium B.C., Aramaic gradually ousted Akkadian as the language of the region, and Akkadian ceased to be spoken sometime around 500 B.C. Some texts in Akkadian continued to be written even until the first century A.D., but the language then fell into oblivion, and was rediscovered only in the nineteenth century, when the cuneiform writing system was deciphered. Today, hundreds of thousands of Akkadian texts have been discovered, encompassing many different genres, including poetry (such as the epic of Gilgamesh), religious compositions, royal and monumental inscriptions, histories, monolingual and multilingual dictionaries (word-lists), grammatical texts, astronomical and mathematical texts, legal documents (such as the Code of Hammurabi), private and diplomatic correspondence, and an endless quantity of economic and administrative documents.

The history of the Akkadian language is conventionally divided into four main chronological periods: Old Akkadian (2500–2000 B.C.), Old Babylonian/Old Assyrian (2000–1500 B.C.), Middle Babylonian/Middle Assyrian (1500–1000 B.C.), and Neo-Babylonian/Neo-Assyrian (1000–500 B.C.). The conventional name 'Old Akkadian' for the earliest attested period is based on the (probably mistaken) assumption that no dialectal variation between the Babylonian and Assyrian idioms existed before the second millennium. The Old Babylonian dialect was considered the classical stage of the language by later generations of Babylonians and Assyrians, and it was the language towards which the later literary idiom (sometimes known as 'Standard Babylonian') aspired.

Grammatical Sketch

During the third millennium B.C., speakers of Akkadian were in prolonged and intimate contact with speakers of the unrelated and typologically dissimilar Sumerian (ergative, agglutinating, verb-final). In consequence, the structure of Akkadian shows an interesting mixture between inherited Semitic features (nominative-accusative alignment, synthetic non-concatenating morphology, noun-modifier order in the NP) with features acquired through convergence (*see* **Language Change and Language Contact**). Such 'Sprachbund' effects are evident especially in the phonology and the syntax, as well as in massive lexical borrowing.

The phonemic system of Akkadian underwent a considerable reduction from the putative Proto-Semitic inventory, with the loss of most of the laryngeal and pharyngeal consonants, probably because of contact with Sumerian. Morphology is the area which shows the least evidence of convergence (although even here, some features, such as the 'ventive' suffix *-am* may be due to Sumerian influence). Nouns have two genders (masculine, feminine), three cases (nominative, accusative, genitive), and show a distinction between singular, plural, and a partly productive dual.

As in the other Semitic languages, verbal morphology is highly synthetic, and based on a system of mostly three-consonantal roots and internal vowel patterns, combined with prefixing, suffixing, infixing, and gemination. The root **p-r-s** 'cut', for instance, appears in forms such as *i-prus* (3SG-cut.PAST), *purs-ā* (cut.IMPERATIVE-2PL), *a-parras* (1SG-cut.-NON PAST), *pars-at* (cut.STATIVE-3FSG), *i-pparis* (3SG-cut.PAST.PASSIVE), *nu-šapras* (1.PL-cut.NON PAST.CAUSATIVE).

Where Akkadian morphology diverges significantly from the other (and later attested) Semitic languages, especially in its so called 'stative conjugation,' Akkadian seems to present an earlier situation. The 'stative' has its origin in conjugated forms of the predicative adjective, but it gradually acquired verbal features. In Akkadian, the stative had not yet become a fully verbal form, but in the other Semitic languages, it was fully integrated in the verbal paradigm (as the 'perfect'), and this led to a restructuring in the tense-aspect system. The morphology of Akkadian remained fairly stable until the first millennium B.C., when the weakening and loss of final syllables led to the disintegration of the case system on nouns, and to the loss of some distinctions on verbs, and so to the appearance of more periphrastic constructions.

Akkadian is nominative-accusative in both morphology and syntax, and generally has dependent marking, although the verb has obligatory subject agreement as well as direct and indirect object pronominal suffixes. Akkadian word order is interesting, because it can be considered highly 'inconsistent.' Akkadian must have inherited a VSO word-order from Proto-Semitic, and this order is still reflected in archaizing personal-names, especially from the earliest period, such as *Iddin-Sin* (gave:3MSG-Sin – '(the god) Sin gave').

However, undoubtedly because of contact with Sumerian, Akkadian acquired a strict verb-final word order, which is attested from the earliest documents. Both SOV and OSV orders are common, but the only constituents that can follow the verb are the bound object pronoun suffixes (and in later periods finite complement clauses). Nevertheless, inside the noun phrase, Akkadian has retained the characteristic Semitic 'VO' characteristics: prepositions, Noun-Genitive, Noun-Relative, Noun-Demonstrative, Noun-Adjective orders. These apparently inconsistent word-order patterns showed no signs of instability, and were maintained intact for two thousand years.

Sources

An extensive state-of-the art overview and bibliography is Huehnergard and Woods (2004). The standard reference grammar is von Soden (1995); Huehnergard (1997) is a teaching grammar. The two research dictionaries are the encyclopaedic Gelb *et al.* (1956-), and von Soden, (1965–1981). Black *et al.* (1999) is a definitions-only dictionary with the most up-to-date overview of the Akkadian lexicon.

Al-Jurjāni, Abd Al-Qāhir (10th Century A.D.)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Al-Jurjāni is ʔabu Bakr ʕabdu ʔal-qāhir bin ʕabdu ʔal-raħmān bin Muħammad Al-Jurjānī. He was born in Al-Jurjān, a town between Tabaristan and Khurasan in Persia (400?–471H/1007–1078 A.D.). A man of broad erudition, his writing extended to many fields including language, linguistics, eloquence, Qurʔānic studies, and metrics. He composed substantive treatises on each of these topics and was sought after as a teacher in his day. Among his compositions are those on eloquence like *ʔasrār ʔal-balāγah* 'Secrets of eloquence' and *dalāʔil ʔal-ʔiʕdʒāz* 'The proofs of the inimitability (of the Qurʔān)'; and, on Qurʔānic studies, his *ʔal-risālah ʔal-šāfiyah* 'The healing message' and *Šarħ ʔal-fātiħah* '*Explanation of the fātiħah* (the first sura of the Qurʔān)'. On literature, he wrote a book on three Arab poets, and composed six books on linguistic matters. We turn to some of these for brief comments as they recapitulate and exemplify what was established by Al-Khalīl and Sībawayh as the pillars of the study of Arabic.

Al-Khalīl had set in writing his dictionary *Kitāb ʔal-ʕayn* 'the book of *ʕayn*', the pattern for subsequent analyses of Arabic lexica. He had isolated the roots into their radicals and determined that the *ʔasmāʔ* 'names/nouns' and *ʔafʕāl* 'actions/verbs' are limited to not less than three and not more than five radicals for native Arabic words. This has been the key to the analyses of Arabic ever since. It is this fundamental insight that Al-Jurjānī developed in his book called *Kitāb ʔal-miftāħ fiy ʔal-sˤarf* 'The book on the key to derivation'. He takes the forms, like *ʔasmāʔ* 'names/nouns', that derive from them and provides all the roots that are associated with them using the variation on the tri- quadri- quinque-radical stems. In his analysis the tri-radical roots have 10 variations, like *faʕl, faʕal, faʕul*, etc., with examples from *ʕasmāʔ* 'names/nouns' and *sˤifāt* 'descriptions/adjectives'. This is followed by patterns that pertain to *ʔafʕāl* 'actions/verbs' which are limited to the tri-radicals and quadri-radicals and each pattern is determined by the variations that obtain in it, e.g., the tri-radical is limited to seven patterns, but within these variations are included the doubled, the roots with *hamzah* [ʔ] or one of the weak letters, as one of the radicals. This is followed by the tri- quadri- quinque-radicals of which there is only one pattern with its three variants. These basic patterns and their exemplifications are followed by sections on the meaning of the *ʔafʕāl* 'actions/verbs', with more definitions and exemplifications and with a brief mention of some of the phonological processes.

The book *ʔal-dʒumal* 'The sentences' is a treatise that takes the theory of *ʕāmil* 'operator' which Sībawayh had proposed as the basis of desinence. It is in a way a summary and application of his booklet called the *ʔal-ʕawāmil ʔal-miʔah* 'The hundred operators'. In this short treatise he takes the *ʕawāmil ʔal-ʔafʕāl* 'operators of actions/verbs', *ʕawāmil ʔal-ħuruwf* 'operators of particles', and *ʕawāmil ʔal-ʔasmāʔ* 'operators of names/nouns', and exemplifies their operations, with other individual issues like masculine and feminine, etc. Al-Jurjānī was a versatile *savant* and any one of the mentioned areas of expertise he delved into would have been a sufficient occupation for a scholar for a lifetime.

Al-Khalīl (8th Century A.D.)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Al-Khalīl is ʕabdu ʔal-Raħmān ʔal-khalīl ʔibn ʔaħmad ʔal-Farāhīdī, known simply as Al-Khalīl (100–175H/ 719–791 A.D.). Al-Khalīl is a name that is respectfully recognized by Arab scholars as an exemplar of scholarship, citizenship, and fidelity to one's faith. He was born in ʕumān, but lived and taught in Basrah. In his travels to Mecca, almost every other year, he came in contact with a variety of dialects.

By the accounts of the chroniclers, he was an ascetic and a creative genius who devised many ways of looking into the Arabic language and its structure. The metrics of Arabic owe their formulations to him. He contemplated the classical pre- and post-Islamic Arabic poetry and captured its varied rhythms by reducing them to 14 basic meters with their proper identities and proper labels. It is called the science of *ʔal-ʕaruwdˤ*. Although this prosodic feat is enough to immortalize him, Al-Khalīl is also known for other linguistic innovations. One of the most significant innovations is the design of the Arabic lexicon. He found the key to the morphology of Arabic. He proposed that the root system in Arabic was constrained to roots of between two and five radicals, and the roots that went beyond these limits either were made up or were borrowed lexical items. By means of the anagrammatic permutations of the radicals, he considered all the possible permutations of a root in order to capture all the words that might be derived from them, words to which are added the proper inflectional or derivational modifications, for example, the root KTB with all its six possible permutations: ktb, kbt, tkb, tbk, bkt, btk. Some of the results of such permutations were used, others were ignored. A second innovation he introduced was to arrange the dictionary not in the traditional *ʔalif, bāʔ*, *tāʔ*, etc., sequence but phonetically (see Table 1), that is, starting with the throat letters, [ʕ], [ħ], etc., and ending with the lip letters [b], [m], and in the process he systematized the phonology of Arabic. His lexicon is called *Kitāb ʔal-ʕayn* 'the book of *ʔal-ʕayn*'. This lexicon became the model and inspiration for subsequent lexicographers, who copied, incorporated, modified, summarized, and found other ways of accounting for the lexical items of Arabic found in it, but they never overlooked the work of Al-Khalīl.

Khalīl was also a grammarian. He included much phonological, morphological, syntactic, and dialectal material in his lexicon. We have no book on grammar attributed to him, except, some claim, *kitāb ʔal-ʤumal fiy ʔal-naħw*. Many grammatical theories and insights, beyond what is in his lexicon, have found their way into the work of his most prominent student, Sībawayh. Sībawayh is the most revered name among the grammarians of Arabic. In his book, called simply *ʔal-kitāb*, he quotes many of the former and contemporary linguists. The man most frequently quoted in this book is Al-Khalīl. He is quoted over 600 times on various topics of grammar. This bespeaks not only of the close relationship between master and disciple, but of the weight that Sībawayh gave the enduring ideas and grammatical analyses of his master. Al-Khalīl's summation of the life of the mind is expressed in a statement attributed to him, which says: If scholars are not God's saints, then God has no saints.

'Al-Zajjājiy, Abu Al-Qasim (10th Century A.D.)

S I Sara, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

ʔal-Zajjajiy is ʔabu ʔal-Qāsim Ibn ʔisħāq ʔal-Zajjajiy. He was born in sˤaimarah, a town in Khuzistan, Persia. He traveled to Baghdad and studied with some of the more prominent linguists from the Baghdad school of linguistics. They included members from both the Basrah school and the Kuwfah school orientations. To mention just a few of the Basrah school adherents, like Ibn ʔal-Sarrāj (-316H/928), the Younger ʔaxfaš (-315H/927 A.D.), ʔabu ʕaliy ʔal-fārisiy (288–377H/901–987 A.D.), and his teacher ʔal-Zajjāj. Here one comes across a curious twist in nomenclature. He is known by ʔal-Zajjājiy as a reference to and in deference to his teacher ʔal-Zajjāj (241–311H/855–923 A.D.), with whom he studied for a long time. Of the teachers of the Kuwfah school orientation one may mention ʔabu Bakr ʔal-ʔanbāriy (271–328H/884–940 A.D.) and ʔabu Bakr Ibn šuqayr (-317H/929 A.D.). ʔal-Zajjājiy also traveled to Damascus and Makka where he taught and wrote. He died in Tiberias (-340 H/951 A.D.).

Of about 15 books on different aspects of Arabic grammar, his most well known book, and the one that received much attention in his time and later, is *ʔal-ʤumal* 'The sentences' which was much used as a textbook for teaching and learning grammar. It is a simplified grammar of Arabic, not on the scale of Sībawayh, but a clear listing, definition, and exposition of grammatical facts in an orderly fashion with clear examples. Over the years it received a large number of commentaries, over 120, in a variety of ways of exposition or analysis of the whole or a part of it.

One may also mention in this context the often repeated account given in ʔal-Zajjājiy's *Maʤālis ʔal-ʕulamāʔ* 'Scholars' Sessions', session #4, as a source of its authenticity, of the celebrated encounter between Sībawayh the spokesperson for the Basrah school of linguistics and ʔal-kasāʔi the spokesperson of the Kuwfah school before the Caliph ʔal-Rašiyd for a linguistic/grammatical disputation, referred to in the literature as *ʔal-mas ʔalah ʔal-zunburiyyah* 'the hornet's question'. *Gad kuntu ʔaðˤunnu ʔanna ʔal-ʕaGraba ʔašaddu las ʕatan mina ʔal-zunbuwri fa-ʔiða huwa hiyā ʔaw fa-ʔiða huwa ʔiyyāhā* [I thought for sure that the scorpion is of stronger sting than the hornet, then he is she [she being on the subjective case], or then he is her [her being on the objective case]. Sībawayh chose 'she' the subjective case. In all the accounts, ʔal-kasāʔi and his followers faulted Sībawayh to the degree that a bedouin speaker was brought in to resolve the alleged manner of speaking. The informant sided with ʔal-kasāʔi's claim and thus Sībawayh lost the argument. He departed the scene of the debate disappointed.

He was a grammatical analyst, looking for causes of changes and variation in Arabic. He subdivided the syntactic causes into three categories: those that are concerned with teaching, those that are concerned with analogy, and those that are concerned with argumentation, i.e., *ta ʕliymiyyah, qiyāsiyyah*, and *ʤadaliyyah*, respectively. As the case above showed, he delved into the disputes between the two schools of linguistics, Basrah and Kuwfa, and tried to bring understanding to arguments where the two schools differed, for example, whether the *ʔism* 'name/noun' or *fiʕl* 'action/verb' is primary, why there is *ʔiʕrāb* 'desinence' in Arabic and its foundation in *ʔasmāʔ* 'names/nouns' *ʔafʕāl* 'actions/verbs', and what does it mean for the same word to be in *rafʕ*, ending with '[u]', *nasˤb* ending '[a]', and *ʤarr* ending with '[i]' in different contexts, and the whole idea of *θiql* 'heaviness' and *xiffah* 'lightness' in speech. He frequently sided with the Basran opinion. These questions were raised in Sībawayh's book. ʔal-Zajjājiy probed the perennial issues of the day in Arabic linguistics.

Alarcos Llorach, Emilio (1922–1998)

G Haßler, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Emilio Alarcos Llorach was born in Salamanca, Spain, on April 22, 1922, and he died in Oviedo, on January 26, 1998. He started his academic studies in Valladolid where his father Emilio Alarcos García was a professor and continued them in Madrid with the master Dámaso Alonso. He graduated in 1947, with a thesis on the *Libro de Aleixandre* (1948). After teaching in Avilés in 1944, his sojourn in Bern and Basel (1946–1947) where he worked as a lector of Spanish had a decisive influence on his linguistic formation. He became acquainted with scientific approaches that were not well received in Spain, and he contributed to their dissemination in his native country. The full integration of Spanish linguistics into the global field was one of Alarcos's accomplishments. This was manifest, for example, in his meeting with Chomsky in Oviedo in 1992.

After a short period of teaching in Cabra (Córdoba) and Logroño, he was appointed to the chair of historical grammar of Spanish at the University of Oviedo in 1950. Alarcos Llorach continued teaching and living in this city for half a century, until the end of his life.

The numerous disciples he trained in Oviedo and the foundation of the journal *Archivum* testify to the fruitfulness of his activities. In 1972 he was elected to a chair (the sillón B) at the Spanish Academy (Real Academia Española), and he joined this institution a year later. At the time of his death he was the president of the association for the history of the Spanish language (Asociación de Historia de la Lengua Española).

Alarcos Llorach contributed considerably to the dissemination of European structuralism in Spain. First, in his phonology (1950) he used ideas from the Prague school, then, in his structural grammar (1951) by using Hjelmslev's glossematics of the Copenhagen school. Finally, his *Estudios de gramática funcional del español* (1970) were influenced by Martinet. Alarcos put into practice an eclecticism that did not consist of a mixture of different doctrines, but rather one that surged out of his conviction that different approaches to a complex reality such as language were necessary. The highlight of his legacy is his *Gramática de la lengua española* (1994), in which he presented his ideas about the description and explanation of parts of Spanish grammar that were never treated before in monographs.

At the same time Alarcos worked on philological topics and proved that a parallel interest in language and literature could be productive. He demonstrated remarkable literary criticism: *La poesía de Blas de Otero* (1966; first published as a university speech given in Oviedo, 1955) and *Ángel González, poeta* (1969). He could well have spoken with consummate ease about language, but he opted for a literary subject for his inaugural speech at the Spanish Academy (*La lucha por la vida* [1973]; republished in 1982 together with works on García Pavón, Delibes, and Martín Santos). In addition, he published several miscellaneous books, for example the *Ensayos y estudios literarios* (1976) and his booklet *El español, lengua milenaria* (1982); also various works on dialects, mainly on the Asturian and Catalan language, which was his second language, fluently spoken by his mother.

Alarcos emphasized the importance of the study of the history of language. As a disciple of the Menéndez Pidal School, he knew that there could not be any philology without linguistic study, and no complete linguistics without aesthetics or literary studies. In his view, science had to be related to human life.

Alarcos's attitude toward language and its linguistic description was characterized by wise tolerance. He rejected prescriptive or clearly purist judgments on idiomatic facts and on the use of language in contemporary society. He repeatedly ascertained that the only unchanging languages are dead languages.

Alarm Calls

K Zuberbühler, University of St Andrews, St Andrews, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Animals commonly vocalize when threatened by a predator. These signals, usually termed alarm calls (from old Italian *all arme* 'to arms' on the approach of an enemy), have continued to bewilder and fascinate for a number of reasons, the first of which is mainly practical. In animal research, it is often difficult to break down the continuous behavioral stream into discrete and meaningful units, which can be studied systematically. Alarm calls are a rare and noticeable exception. They are highly discrete and easy to identify, making it possible to systematically study both the causes and consequences of behavior. A second motivation, related to the previous one and significant for the evolution of linguistic abilities, relates to the fact that alarm calls provide a unique tool for accessing the cognitive mechanisms underlying an animal's behavior. Finally, alarm calls are interesting because they seem to pose a problem for evolutionary theory. They are often among the most prominent and noticeable signals in a species' repertoire, and it seems paradoxical for individuals to behave conspicuously in the presence of a predator, thereby revealing their presence and location (e.g., Shalter, 1978).

Following these considerations, this article has the following objectives. First, it summarizes research that has dealt with the problem of why animals produce seemingly maladaptive behavior in the presence of a predator. What are the evolutionary processes that have provided a selective advantage to individuals who behave this way? Second, from a cognitive–linguistic perspective, the article seeks to seize the unique opportunity that alarm calls offer, that is, to try to describe the cognitive processes that underlie call production. Several empirical studies are discussed that have aimed to investigate the relationship between the occurrence of an external event (i.e., the appearance of a predator) and the production and comprehension of these signals, particularly in the nonhuman primates. No attempt is made to provide a systematic overview of alarm calling in the various taxonomic groups, however. Instead, a handful of empirical studies have been selected, particularly those that are likely to inform the linguistically interested reader about core cognitive phenomena in nonhumans and their potential relevance for the evolution of linguistic capacities in humans.

The Evolution of Alarm Calls

Three main groups of evolutionary hypotheses have been put forward to explain why animals produce conspicuous vocalizations in the presence of a predator. First, attention-grabbing behavior in the presence of a predator can provide a selective advantage to the signaler if it increases the survival chances of closely related kin (Maynard Smith, 1965). Calling may be risky, but under this hypothesis, the costs are outweighed by the benefits of increased survival of recipients who carry a proportion of the caller's genes (the kin selection hypothesis). Second, alarm calling is beneficial to a signaler if it increases the reproductive success of the caller (the sexual selection hypothesis). Third, alarm calling is beneficial if it elicits behavior in others that decreases the vulnerability of the caller directly (the individual selection hypothesis). Within this third hypothesis, two scenarios have been proposed. The first one considers the effects of alarm calling on conspecific recipients (the prey manipulation hypothesis). Here, calling is costly at the beginning of a predator–prey interaction, but quickly

Introduction

Animals commonly vocalize when threatened by a predator. These signals, usually termed alarm calls (from old Italian *all arme* 'to arms' on the approach of an enemy), have continued to bewilder and fascinate for a number of reasons, the first of which is mainly practical. In animal research, it is often difficult to break down the continuous behavioral stream into discrete and meaningful units, which can be studied systematically. Alarm calls are a rare and noticeable exception. They are highly discrete and easy to identify, making it possible to systematically study both the causes and consequences of behavior. A second motivation, related to the previous one and significant for the evolution of linguistic abilities, relates to the fact that alarm calls provide a unique tool for accessing the cognitive mechanisms underlying an animal's behavior. Finally, alarm calls are interesting because they seem to pose a problem for evolutionary theory. They are often among the most prominent and noticeable signals in a species' repertoire, and it seems paradoxical for individuals to behave conspicuously in the presence of a predator, thereby revealing their presence and location (e.g., Shalter, 1978).

Following these considerations, this article has the following objectives. First, it summarizes research that has dealt with the problem of why animals produce seemingly maladaptive behavior in the presence of a predator. What are the evolutionary processes that have provided a selective advantage to individuals who behave this way? Second, from a cognitive–linguistic perspective, the article seeks to seize the unique opportunity that alarm calls offer, that is, to try to describe the cognitive processes that underlie call production. Several empirical studies are discussed that have aimed to investigate the relationship between the occurrence of an external event (i.e., the appearance of a predator) and the production and comprehension of these signals, particularly in the nonhuman primates. No attempt is made to provide a systematic overview of alarm calling in the various taxonomic groups, however. Instead, a handful of empirical studies have been selected, particularly those that are likely to inform the linguistically interested reader about core cognitive phenomena in nonhumans and their potential relevance for the evolution of linguistic capacities in humans.

The Evolution of Alarm Calls

Three main groups of evolutionary hypotheses have been put forward to explain why animals produce conspicuous vocalizations in the presence of a predator. First, attention-grabbing behavior in the presence of a predator can provide a selective advantage to the signaler if it increases the survival chances of closely related kin (Maynard Smith, 1965). Calling may be risky, but under this hypothesis, the costs are outweighed by the benefits of increased survival of recipients who carry a proportion of the caller's genes (the kin selection hypothesis). Second, alarm calling is beneficial to a signaler if it increases the reproductive success of the caller (the sexual selection hypothesis). Third, alarm calling is beneficial if it elicits behavior in others that decreases the vulnerability of the caller directly (the individual selection hypothesis). Within this third hypothesis, two scenarios have been proposed. The first one considers the effects of alarm calling on conspecific recipients (the prey manipulation hypothesis). Here, calling is costly at the beginning of a predator–prey interaction, but quickly

becomes outweighed by the benefits accrued by other individuals' antipredator responses. A good example is the turmoil caused by individuals escaping when hearing an alarm call, creating a cloud of confusion for the predator from which the caller can benefit. However, in some cases animals give alarm calls in the absence of a conspecific audience, suggesting that the behavior has evolved for other purposes. A popular idea here is that some predators are affected by the alarm calls directly, without the intermediate step of other prey behavior (the perception advertisement hypothesis). This is especially the case for predators who depend on unprepared prey. Particularly in the bird literature, the term 'mobbing call' is sometimes used, mainly to refer to cases where alarm calls are part of more elaborate displays, involving conspicuous locomotory behavior in the presence of the predator.

It is important to point out that the three hypotheses are not mutually exclusive but may operate alongside each other in various ways. In the following sections, selected empirical findings that support one or several of the selective forces underlying the evolution of alarm calling are discussed.

Alarm Calls Favored by Kin Selection

One recurrent finding is that alarm callers are susceptible to the type of audience present (e.g., Karakashian *et al.*, 1988). A first solution to the apparent alarm call paradox is, therefore, that individuals call preferentially when close genetic relatives are nearby. Under such circumstances kin selection theory can explain the evolution of conspicuous signaling in the presence of predators. The reasoning is that costly alarm calling can still be beneficial if it improves the survival of individuals that share a certain proportion of the caller's own genes. One testable prediction is that individuals produce alarm calls as a function of the number of close relatives in the audience. The empirical evidence for the kin selection hypothesis is strongest for the parent–offspring relation (e.g., Blumstein *et al.*, 1997), and alarm calling in this context may be conceptualized as a form of altruistic parental care.

A related but empirically more challenging endeavor is based on the assumption that callers inevitably share high degrees of genetic relatedness with some other nondescendent kin, such as brothers and sisters. If kin selection operates as a selective force, then individuals should be just as willing to engage in risky alarm call behavior if it increases the survival chances of closely related nondescendent kin, apart from that of their own offspring, as long as they are sufficiently closely related to one another. Much empirical effort has been devoted to this topic, particularly in various rodent species, but the overall picture is incoherent. Males and females often differ in their alarm calling in the presence of nondescendent kin, suggesting that kin selection may have affected individuals in sex-specific ways. For example, in Gunnison's prairie dogs, *Cynomys gunnisoni*, females with nearby nondescendent kin call more often to a ground predator than females without nondescendent kin. Males commonly produce alarm calls, but calling is unrelated to kinship of nearby listeners (Hoogland, 1996). A nondescendent kin audience may enhance alarm calling to particular predator types only, but patterns vary from one species to the next. For example, Belding's ground squirrels, *Spermophilus belding,* show kin-sensitive response to terrestrial but not to aerial predators, where the caller's own exposure appears to be the main factor (Sherman, 1977, 1985). Conversely, the opposite pattern was found in Columbian ground squirrels (*Spermophilus columbianus*) (Macwhirter, 1992). In this species, females with offspring were more likely than other females to give alarm calls in response to a ground predator, but females did not behave nepotistically toward other nondescendent kin. However, females were more likely to emit alarm calls in response to aerial predators if close nondescendent kin were in the colony.

Kin selection has also been put forward as an explanation for the evolution of alarm calls in nonhuman primates, although the overall evidence is weak, at least for benefiting nondescendent kin. For example, spider monkeys alter their alarm call behavior as a function of the number of kin in the vicinity (Chapman *et al.*, 1990). Similarly, Kloss's gibbons produce alarm calls that can be heard in neighboring home ranges, which are often occupied by the callers' close relatives, suggesting that these calls may warn not only members of the immediate family, but also neighboring relatives (Tenaza and Tilson, 1977).

The emerging picture of the role of kin selection is that (a) alarm calling is clearly affected by the presence of descendent kin, and as such is a common aspect of parental care, and (b) in some species, kin selection may have additionally favored alarm calling to benefit a nondescendent kin audience, but no general patterns have emerged. In cases in which individuals' alarm calls appear to warn nondescendent relatives, kin selection seems to have acted in various idiosyncratic ways.

Alarm Calls Favored by Sexual Selection

Animals often give alarm calls when no kin are nearby, requiring a different set of evolutionary explanations. One set is built on the idea that alarm calls are sexually selected signals produced by males as part of

their attempts to increase their reproductive success (Zuberbühler, 2002). According to Darwin (1871), sexual selection "... depends, not on the struggle for existence, but on a struggle between the males for possession of the females; the result is not death of the unsuccessful competitor, but few or no offspring." In these cases, however, sexual selection must have acted as a secondary evolutionary force on communication systems in which alarm calls have already been present.

The sexual selection hypothesis is currently supported by a number of observations relating to alarm call structure and usage. In some species, males are more likely to produce alarm calls while in the presence of unrelated females than to other audiences (e.g., Evans *et al.*, 1994), suggesting that alarm calls may be part of a mating strategy to enhances the caller's reproductive success. Similarly, male vervet monkeys (*Cercopithecus aethiops*) alarm call at higher rates in the presence of adult females than adult males (Cheney and Seyfarth, 1990). In some species, not only do adult males differ from other age/sex classes in terms of call usage, but their alarm calls are also structurally different from those of the adult females. For example, it has long been known that the adult males in many forest monkey species produce conspicuous loud calls in response to predators, which carry over remarkable distances (e.g., Gautier and Gautier, 1977). Recent research on West African Diana monkeys, *Cercopithecus diana,* and other forest primates has shown that these calls function as predator alarm calls (Zuberbühler, 2002, 2003). Diana monkeys live in small but stable social groups with one adult male and several adult females with their offspring (Uster and Zuberbühler, 2001). The monkeys are hunted by leopards (*Panthera pardus*) and crowned eagles (*Stephanoaetus coronatus*), and both the adult male and the females produce conspicuous alarm calls to these two predators. However, the calls of the males are structurally different from those of the females. They are low-pitched, high-amplitude signals given in repeated bursts, which carry over long distances through dense tropical forest habitat, sometimes up to one kilometer (Zuberbühler, 2003) (**Figure 1**).

A number of observations support the hypothesis that these male alarm calls have been under pressure by sexual selection. Polygynous social systems, in which one adult male mates with several adult females, are notorious for sexually selected conspicuous male traits, including vocalizations (Clutton-Brock and Albon, 1979). In these social systems, male competition over females is especially high, which typically leads to the evolution of male traits that are useful in male–male competition or that females find attractive (Anderson, 1994). In polygynous monkeys, such as the Diana monkey, males typically try to take over a group of females and mate with them for some time until replaced by another male. If females are able to exert some choice over tenure length of a particular male, then one might expect to see a relation between female tolerance toward the male and how committed he is to engaging in antipredator behavior, such as producing costly alarm calls in the presence of a predator (Eckardt and Zuberbühler, 2004). An alternative explanation is that sexual selection has usurped male alarm calls and transformed them into signals effective in male–male competition. The fact that the male alarm calls carry over very long distances suggests that the intended recipients are not just the male's own group members (which are usually within about 100 m), but also single males roving through the forest or subadult males in neighboring groups. By making their presence and vigor known, tenured males may avoid costly encounters with these males in search of a group of females.

It is interesting to note that during puberty several developmental changes occur in the vocal behavior of male Diana monkeys and other guenons, specifically a drop in pitch and the loss of some of the juvenile vocal repertoire (Gautier and Gautier, 1977). In the Taï forest, Ivory Coast, subadult male Diana monkeys go through a phase in which their alarm shows remnants of a female alarm call as well as the first emerging elements of a fully developed male loud call, suggesting that males go through a transition phase when their calls develop from female alarm calls to male loud calls (Zuberbühler, 2002), a further sign that sexual selection has acted secondarily on the structure and usage of male monkey alarm calls.

Strong evidence for the sexual selection hypothesis is not yet available, although the hypothesis makes various testable predictions. For example, for females to be able to exert a choice, male alarm calls must be individually distinctive, perhaps more so than their own calls. In Diana monkeys, this is certainly the impression one gets after listening to various recordings. Another prediction might be that after a new male takes over, he ought to be especially eager to demonstrate his commitment to antipredator defense by producing large numbers of alarm calls. One such case has been documented in putty-nosed monkeys (*Cercopithecus nictitans*; Eckardt and Zuberbühler, 2004).

Alarm Calls Favored by Individual Selection

Both kin selection and sexual selection suggest that alarm calling provides a net benefit to the caller because it increases the survival chances of close genetic relatives or the reproductive success of the caller. However, in some cases callers may also

Figure 1 Spectrographic representations of the predator alarm calls of male and female Diana monkeys in the Taï Forest, Ivory Coast. Reproduced with permission.

enjoy direct benefits from their actions in terms of their own survival. This is the case if alarm calls elicit collective antipredator behavior in nearby recipients, which confuses or disorients the predator (the prey manipulation hypothesis) (e.g., Charnov and Krebs, 1975).

An alternative idea is that alarm calls directly interfere with the predator's hunting tactic, for example, if predators depend on unwary prey (the perception-advertisement hypothesis), (e.g., Bergstrom and Lachmann, 2001). Recently, this version of the individual selection hypothesis has received some empirical attention. Work on free-ranging Diana monkeys has shown that some primate alarm calls function to advertise perception to predators that rely on unprepared prey, such as leopards (Zuberbühler and Jenny, 2002) and crowned eagles (Shultz and Noë, 2002). Playback experiments have demonstrated that the presence of crowned eagles and leopards reliably elicited high rates of conspicuous alarm calls in Diana monkeys, whereas playbacks of two other equally dangerous predators, chimpanzees (*Pan troglodytes*) and human poachers, never did (Zuberbühler, 2003). The most likely explanation for these striking differences in alarm call usage is that chimpanzees and humans, but not leopards or eagles, are able to pursue monkeys in the trees, which greatly increases the costs of conspicuous alarm calling. A follow-up study involving most other primate species in the Taï Forest indicated that the pattern described for the Diana monkeys is also accurate for other monkey species (Zuberbühler, 2003; Figure 2).

But are these alarm calls really effective in deterring monkey-hunting leopards? To investigate whether or not this is the case, the hunting behavior of a number of wild leopards in the Taï forest has been monitored with the help of radio-tracking equipment (Zuberbühler, 2003; Zuberbühler and Jenny, 2002). Results have shown that forest leopards hunt monkeys by approaching unwary groups and hiding in their vicinity, presumably to wait for individuals to descend to the ground. Once the monkeys detected a

hiding leopard, however, they invariably began to produce alarm calls at very high rates, which typically caused the leopard to leave the area (Figure 3), showing that these alarm calls function to advertise perception and to deter the stalking leopards.

The Cognitive Bases of Alarm Calls

The previous section addressed the problem of why animals produce conspicuous alarm calls in the presence of a predator; the remainder of the article deals with the cognitive processes involved in alarm call production and perception. The focus is on empirical evidence that is perhaps most relevant for the linguistically interested reader: the kinds of cognitive abilities nonhuman primates recruit when processing their own vocalizations. Results are relevant to assess whether or not these abilities are akin to those involved in speech processing in humans. Theories of language origins have to explain how the highly complex and sophisticated cognitive capacity required for language processing has evolved in an extremely short period of time. Several lines of evidence suggest that humans did not have the anatomical and neural prerequisites to produce modern speech until very recently (Lieberman, 2000; Enard *et al.*, 2002). One implication is that many of the cognitive capacities required for language are phylogenetically much older, having evolved in the primate lineage long before the advent of modern humans and for reasons other than language production. An empirical investigation of the cognitive capacities of our closest living relatives, the nonhuman primates, is therefore of particular interest, because they may shed light on the evolutionary origins of cognitive processes underlying speech. Of particular interest are semantic and syntactic abilities, as they are central to virtually every definition of language (Crystal, 1997). Three aspects are dealt with: (a) the structure of alarm calls, (b) how they are being used in particular circumstances, and (c) the kinds of mental processes that recipients activate when responding to them.

Alarm Call Structure

The fact that an animal produces different types of alarm calls alone is not a particularly exciting finding; it has been demonstrated in many groups of animals, primates and nonprimates alike (e.g., *nonprimates*: Slobodchikoff *et al*., 1991; Blumstein and Arnold, 1995; Gyger *et al*., 1987; e.g., *primates*: Struhsaker, 1967; Macedonia and Evans, 1993; Fichtel and Kappeler, 2002; Eckardt and Zuberbühler, 2004). In primates, and probably most other groups, alarm call production appears to be under relatively tight genetic control, with callers having little flexibility for structural modification (see Blumstein, 1999). For example, infant vervet monkeys rarely produce alarm calls, but if they do, their alarm calls are acoustically similar to those of adult animals (Seyfarth and Cheney, 1997). Their vocal stiffness is the product of very limited control over the articulators, particularly the tongue (Riede *et al*., 2005). Although some flexibility is possible, nonhuman primates simply do not have sufficient command over the geometry of their vocal tracts to deliver the extensive array of phonemes that bring about human speech.

How exactly the different acoustic structures emerge in the different animal species may not be a random affair. Marler (1955) has argued that some animals have evolved alarm calls with acoustic features that make it hard for predators to detect the caller. The classic example is a passerine aerial predator alarm, the "seeet" call, which humans find hard to locate. However, experimental work has shown that several raptors are able to accurately orient toward the source of playback recordings of passerine "seeet" calls, although the response rates were somewhat lower compared to other alarm call types (Shalter, 1978). Whether this was a result of the raptors' experiencing perceptual difficulties, as Marler argued, or whether the raptors were simply less motivated to orient toward "seeet" calls because they indicated that the prey was alert, as Shalter argued, is an unresolved issue.

Another line of reasoning refers to the idea that there is an inherent relation between an individual's psychological state and the acoustic structure of the vocalizations it produces, the so-called motivational-structural rules (Morton, 1977). Here, the proposition is that individuals give low-frequency atonal vocalizations when prepared to assail an opponent. High-frequency tonal vocalizations, in turn, are more likely to be linked with an intention to withdraw. As predators differ in the kinds of threat they pose, and the most adaptive strategies to counteract them, this line of reasoning may also explain some acoustic patterns in alarm calls (see following discussion).

Alarm Call Usage

From a comparative cognitive perspective, studies of call usage are of some interest because it is sometimes possible to determine what aspects of the environment an individual responds to when giving alarm calls. Particularly enlightening work has been conducted on domestic chickens (*Gallus domesticus*). Cockerels produce acoustically distinct alarms to raptors and ground predators, suggesting that these alarm calls might function as labels for certain predator classes. However, experiments have shown that callers mainly respond to a predator's direction of attack, regardless of its biological class. For example, when a picture of a raccoon, a typical ground predator, is moved across an overhead video screen, cockerels respond with aerial alarm calls, which they normally give to raptors (Evans *et al*., 1994). Similarly, although some species of squirrels produce acoustically distinct alarm calls, they also appear not to respond to the predator category *per se,* but instead to the relative distance and threat imposed by the predator (e.g., Leger *et al*., 1980). The squirrels' alarm call system is hence capable of encoding the degree of urgency that a caller assigns to a particular event. Similar findings have been reported from other species, such as Arabian babblers (*Turdoides squamiceps*; Naguib *et al*., 1999) and yellow-bellied marmots (*Marmota flaviventris*; Blumstein and Armitage, 1997), both of which produce acoustically distinct alarm calls but do not assign them systematically to particular types of predators.

This naturally raises the question of whether or not it is appropriate to assume that monkey alarm calls are labels for different types of predators, in the sense that they encode the biological class of predators. Similar to chickens or marmots, monkeys may simply respond to the momentary threat imposed by a predator, regardless of its biological class. Here, alarm calls may be reflections of a caller's momentary perceived threat, rather than true labels of external events. To distinguish between the two hypotheses, the following playback experiment was conducted with Diana monkeys. Recordings of eagle shrieks or leopard growls were broadcast from a concealed speaker to various wild groups throughout the Taï forest. The position of the speaker was altered systematically such that groups differed in how they encountered the alleged predator. In some cases, the predator vocalizations, either eagle shrieks or leopard growls, were either close or far, or played from below or from above, resulting in eight different playback conditions. Monkeys consistently responded to the predator category represented by the playback stimuli, regardless of immediate threat or direction of

attack. Similar findings were later reported from closely related Campbell's monkeys, *Cercopithecus campbelli*, suggesting that nonhuman primates generally label the biological class of a predator, regardless of momentary discrepancies in degrees of threat (Zuberbühler, 2003).

How does an individual monkey learn to use the leopard alarm call to leopards, but not to snakes? Not much is known about how monkeys learn to use their alarm call repertoire. Some observational data are available from free-ranging vervet monkeys. Although monkeys come in contact with over 150 species of birds and mammals, only a small proportion of these species pose a threat (Seyfarth and Cheney, 1997). One intriguing observation has been that infant vervet monkeys do not appear to apply their innately encoded set of alarm calls randomly to these various groups of animals. Instead, infants give eagle alarm calls only to birds and objects in the air, but never to terrestrial animals (Cheney and Seyfarth, 1990). Similarly, infants initially give leopard alarm calls to a variety of species on the ground, most of which do not pose any danger to them. One interpretation has been that primates are predisposed from birth to divide other animals into a few main groups and then learn to restrict call usage to a small number of relevant predator classes (Seyfarth and Cheney, 1997). Thus, alarm calls appear to be the output of certain psychological states, which are invoked by certain types of events. During maturation monkeys learn to restrict call use to those few species that pose a threat to them. This may also explain why alarm call production is so uniform across various populations in a given species.

In this sense, alarm call production might be analogous to nonlinguistic human utterances, such as laughing. Whether or not an event is perceived as amusing is the result of a cognitive process that draws on various memories. Once it qualifies, people will inadvertently experience amusement, and laughing will be difficult to suppress.

The following observation may illustrate the point. In a group of Campbell's monkeys, housed at the Paimpont Primate Research Station of the University of Rennes, a captive-born adult male was observed to produce eagle alarm calls during an aggressive interaction with a group of DeBrazza's monkeys (*Cercopithecus neglectus*), housed in the adjacent cage (Zuberbühler, unpublished data). During the interaction, the male was vigorously shaking the fence, trying to assault the neighboring individuals, a behavior regularly seen in free-ranging males interacting with predatory crowned eagles. Eagle alarm calls, in other words, may be the vocal manifestation of an extremely aggressive motivation on behalf of the male, which in the wild is typically elicited by the appearance of a crowned eagle. The captive male, having never had the opportunity to interact with an eagle, produced the calls during an aggressive interaction with another monkey species.

Alarm Call Comprehension: Conspecific Calls

What kinds of mental representations do individuals activate as recipients of alarm calls, that is, when hearing another individual's calls? One answer comes from a classic study conducted on East African vervet monkeys. In this species, individuals produce acoustically different alarm calls to at least five different types of predators: large terrestrial carnivores, eagles, snakes, baboons, and unfamiliar humans (Seyfarth and Cheney, 1997; Struhsaker, 1967). Playback experiments have demonstrated that some of these calls elicit in other monkeys antipredator responses that resemble their natural response to the corresponding predators. For example, playbacks of eagle alarm calls cause monkeys to look up into the air or run into a bush (Seyfarth *et al.*, 1980; Struhsaker, 1967). In the meantime, similar findings have been reported from other monkey species. As mentioned previously, Diana monkey males and females produce acoustically different alarm calls to crowned eagles and leopards. When hearing a male's alarm calls, nearby females respond with their own corresponding alarm calls, suggesting that the calls contain information about the type of predator present (**Figure 4**).

What kinds of mental representations are responsible for the monkeys' behavior? A cognitively simple model might suggest that the females' response is based on rather superficial processing: individuals respond to the physical features of alarm calls without accessing any of their potential associated meanings. Alternatively, alarm call processing might be more akin to that of linguistic information processing. In human language, speech sounds are not just processed at the peripheral acoustic level, but in relation to the types of cognitive structures they refer to, which are shared by both the signaler and the recipient (e.g., Yates and Tule, 1979).

Under field conditions, questions concerning mental processes are difficult to address, mainly because the choice of experimental techniques is so limited. One paradigm has turned out to be of significant value: the prime-probe technique. It is a variant of the habituation–dishabituation procedure initially developed for prelinguistic children (Eimas *et al.*, 1971), but differs from it because it does not have a long habituation phase. Instead, animals are provided with a one-time exposure to some critical information

Figure 4 Diana monkey responses to playbacks of predator vocalizations presented with varying degrees of threat: (A) distance, (B) direction of attack. Reproduced from Zuberbuhler K (2000). *Animal Behaviour 59(5)*, 917–927, with permission of Elsevier.

and then tested on the effect of this manipulation of their subsequent response to an experimental probe stimulus. Figure 5 illustrates the design used to investigate whether Diana monkeys process alarm calls by accessing mental representations of associated predator classes.

In each trial, the playback speaker was positioned in the vicinity of a monkey group. Monkeys were primed with either predator vocalizations (baseline) or alarm calls (test and control). After a five-minute period of silence, the probe stimulus was broadcast. Baseline, test, and control conditions differed in the types of changes between prime and probe stimulus. In the baseline condition, both the acoustic and semantic features were alike. The prediction was that subjects would produce many alarm calls to the prime stimulus but only few calls to the probe stimulus because both the acoustic and the semantic information were repeated. In the test condition, subjects heard alarm calls followed by vocalizations of the *corresponding* predator. In this condition, the semantic features remained the same, whereas the acoustic features changed. Subjects were expected to respond to the probe by producing (a) many alarm calls (if they attended to the acoustic-perceptual features) or (b) few alarm calls (if they attended to the semantic-conceptual information). Finally, in the control condition, both the acoustic and the semantic features changed. Subjects heard an alarm call followed by the call of the *noncorresponding* predator. Because both the acoustic and the semantic features changed, subjects were expected to produce many alarm calls to both the prime and the probe stimuli, regardless of how they processed the calls.

Results showed that the semantic content of the prime stimuli, not their acoustic features alone, explained the response patterns of the monkeys to the probe stimuli (Zuberbühler, 2003). That is, both eagle shrieks and leopard growls, two very powerful stimuli, lost their effectiveness in eliciting alarm calls when subjects were primed with the corresponding male alarm calls. Figure 6 illustrates the effect in response to the crowned eagle.

In conclusion, this experiment suggests that only variation in the semantic properties mattered to the monkeys when reacting to the vocalizations. Primates, in other words, appear be able to process alarm calls on a conceptual–semantic rather than a perceptual–acoustic level (Cheney and Seyfarth, 1990).

Alarm Call Comprehension: Eavesdropping

Primates are highly attentive to the alarm calls of other species. Vervet monkeys (*Cercopithecus aethiops*), for example, respond to superb starlings' (*Spreo superbus*) terrestrial and raptor alarm calls as a function of the calls' referential space – the natural range of predators that typically elicit the alarm calls. Young vervet monkeys need several months to learn to fully interpret starling alarm calls (Cheney and Seyfarth, 1990). Taï forest monkeys respond to the alarm calls of several nonprimate species that are hunted by leopards, such as various species of squirrels and duikers. One interpretation is that the monkeys have a fairly sophisticated understanding of the causes that determine another species' alarm call behavior. Interspecies communication, in other words, may provide additional valuable opportunities to investigate the cognitive mechanisms underlying monkey alarm call processing.

To investigate whether monkeys are able to attend to the most likely cause of an alarm call, as opposed to responding directly to the alarm call itself, the following experiment was conducted. Crested guinea fowls (*Guttera pucherani*), a gregarious ground-dwelling forest bird, produce alarm calls to a series of ground predators, including humans and leopards. When hearing guinea fowl alarm calls, Diana monkeys typically respond with leopard alarm calls,

Figure 5 Design of the playback study: Monkey groups are primed with eagle- or leopard-related stimuli and then tested with eagle shrieks. Baseline, test, and control condition differ in the acoustic and semantic similarity of the prime and probe stimuli. X-axes of spectrograms represent time(s), y-axes represent frequencies (kHz). Figure 6 Results of the prime-probe experiments using eagle shrieks as probe stimuli. Histograms represent the median number of eagle alarm calls (hatched) or leopard alarm calls (solid) given in the first minute after a playback stimulus. Error bars indicate the values of the third quartile of the data set. The points connected by lines between them represent the median alarm call rate during the five-minute period of silence in between two playback stimuli. Using leopard growls as a probe stimulus yielded analogous results. Reprinted from Zuberbuhler K, Cheney D L & Seyfarth R M (1999). *Journal of Comparative Psychology 113*, 33–42. Copyright 1999 by the American Psychological Association. Reproduced with permission.

suggesting that the monkeys associate guinea fowl alarm calls with the presence of a leopard. However, crested guinea fowls sometimes give the same alarm calls to humans, which appears to place the monkey in a behavioral dilemma: the best antipredator response to humans is to remain silent to avoid detection, whereas the best response to leopards is produce a large number of alarm calls to advertise perception.

To make the appropriate decision, Diana monkeys have to be able to draw some inferences about the possible causes of the birds' alarm calls. To investigate the monkeys' level of causal understanding, different groups of Diana monkeys were primed to the presence of a leopard or a human poacher by playing back brief recordings of either leopard growls or human speech in the vicinity of a monkey group. Then, after a five-minute period of silence, the same group was exposed to playbacks of guinea fowl alarm calls. If the monkeys are able to draw inferences about the potential causes of guinea fowl alarm calls, then they should response with alarm calls after being primed with leopard growls, but not after being primed with human speech. However, if the monkeys have simply learned to associate guinea fowl alarm calls with the presence of a leopard (as their natural response seems to suggest), then their response to guinea fowl alarm calls should not differ between the two conditions. Results revealed significant differences in the way leopard-primed and human-primed Diana monkey groups responded to guinea fowl alarm calls, suggesting that the monkeys' response was not driven by the guinea fowl alarm calls themselves, but by their momentary beliefs of the type of predator most likely to have caused the birds to give alarm calls (Zuberbühler, 2003).

A similar problem exists when the monkeys are confronted with a nearby group of chimpanzees, a dangerous predator (Boesch and Boesch-Achermann, 2000). But chimpanzees are occasionally attacked and preyed upon by leopards themselves (Boesch and Boesch-Achermann, 2000; Zuberbühler and Jenny, 2002). When this happens they give loud and conspicuous alarm calls, the 'SOS' screams (Goodall, 1986). When chimpanzee SOS screams were broadcast to different groups of Diana monkeys, about half of all the groups tested switched from a chimp-specific cryptic response to a leopard-specific conspicuous response (see Figure 2), suggesting that in some groups individuals assumed the presence of a leopard when hearing the chimpanzee alarm screams. Interestingly, Diana monkey groups with a home range in the core area of a resident chimpanzee community were significantly more likely to do so than peripheral groups, which were more likely to respond cryptically, suggesting that Diana monkey groups differ in semantic knowledge of chimpanzee vocal behavior (Zuberbühler, 2003; Figure 7).

Interspecies communication not only occurs between predator and prey but also between different species of primates. For example, ring-tailed lemurs (*Lemur catta*) respond appropriately not only to their own alarm calls but also to playbacks of the alarm calls of sympatric sifakas (*Propithecus verreauxi*; Oda and Masataka, 1996). The Taï monkeys regularly forage in mixed species groups to improve their protection against predation, and it is therefore not surprising that individuals of mixed species groups respond to each other's alarm calls, such as in the case of the Diana monkey–Campbell's monkey association (Wolters and Zuberbühler, 2003). Male Campbell's monkeys produce two acoustically different alarm calls to crowned eagles and leopards. Playbacks of Diana monkey alarm calls to Campbell's monkeys and vice versa reliably elicited the appropriate alarm responses in the other species (Zuberbühler, 2003). This ability, however, may not be a uniquely primate capacity. Recent playback experiments with yellow-casqued and black-casqued hornbills showed that these birds readily distinguish between Diana monkey eagle and leopard alarm calls (Rainey *et al.*, 2004).

Figure 7 Relationship between a Diana monkey group's tendency to respond with leopard alarm calls to chimpanzees' SOS screams and the location of their home range within the resident chimpanzees' territory. Chimpanzee social screams did not elicit any alarm calls. Reproduced from Zuberbuhler K (2000). *Animal Behaviour 59(5)*, 917–927, with permission from Elsevier.

However, primates may be unique in their abilities to attend to the semantic properties of other species' alarm calls. For example, in a prime-probe experiment similar to the one presented earlier (Figure 5), Diana monkeys have been shown to process the semantic features of the Campbell's alarm calls analogous to how they process their own calls (Zuberbühler, 2003). Further work on the Campbell's–Diana monkey system showed that alarm calls undergo semantic adjustments in the minds of the recipients, depending on the sequencing of alarm

calls. As mentioned earlier, Campbell's monkey males give acoustically distinct alarm calls to leopards and crowned eagles, and Diana monkeys respond to these calls with their own corresponding alarm calls. However, in less-dangerous situations, Campbell's males often emit a pair of low, resounding 'boom' calls before their alarm calls. Playbacks of boom-introduced Campbell's eagle or leopard alarm calls no longer elicited alarm calls in Diana monkeys, indicating that the booms have affected the semantic specificity of the subsequent alarm calls, suggesting that monkeys are able to attend to simple syntactic cues when responding to each other's alarm calls (Zuberbühler, 2003).

Is it reasonable, therefore, to liken these animal signals to human words? After all, they share one of the most fundamental properties, the ability to transmit accurate acoustic information about an external event, which is subsequently decoded by insightful recipients. Still, most researchers have remained cautious when interpreting these kinds of data, even in the case of primates. The reason for that stems from a fundamental discrepancy between the cognitive processes driving alarm call production and those governing their perception. There is simply no evidence that, when producing an alarm call, nonhumans are actively trying to inform each other about the events they have just witnessed. Instead, primate behavior appears to be the result of a caller's egocentric interaction with the world, although in some cases the signals happen to reliably and uniquely denote an external event. For this reason, it has been argued that animal alarm calls are merely functionally referential (or semantic), in contrast to true or intentional referentiality, which presumably underlies human speech. Nevertheless, it would be interesting to know how ubiquitously human speech production is intentionally guided, as opposed to speakers' simply knowing which bits of language are used appropriately in which circumstances.

Conclusions

Alarm calling is found in a large number of species, demonstrating its adaptive value in predation avoidance. It is also intriguingly absent in others, such as some nocturnal prosimians (E. Bramley, personal communication), suggesting that alarm calls are a product of sociality. There is evidence that alarm calls are or have been under the influence of all major selective forces (i.e., individual, kin, and sexual selection), although it is difficult to identify general patterns concerning the importance of these forces.

In nonhuman primates, alarm calling is the result of complex cognitive processes, particularly in the mind of the recipient. Nonhuman primates are highly attentive to stimuli that predict the presence of a predator, and they have demonstrated astonishing skills in solving predation-related problems. This is interesting because predation is an ecological force usually thought to have led rather basic and rigid behavioral patterns, but not to higher cognitive abilities (Humphrey, 1976). For nonhuman primates, this might have been a misconception because in many of the experiments discussed here, monkeys were showing behavior that resulted from seemingly higher cognitive processes, such as inference making, causal understanding, semantic and syntactic processing, and rapid association learning. Predation, in other words, might have provided a strong selection pressure to favor the evolution of higher intellectual faculties in nonhuman primates. The way they produce, use, and interpret their own and other species' alarm calls is a clear manifestation of this intelligence.

Acknowledgments

Much of the field research reviewed in this article was made possible by grants from the University of Pennsylvania, the U.S. National Science Foundation, the Leakey Foundation, the National Geographic Society, the Max Planck Society, the Swiss National Science Foundation, the European Science Foundation (OMLL), and the British Academy. I thank all of them for their generous support.

The Republic of Albania (Republika e Shqiperise) is situated in the southern Balkans and borders Greece to the south, Macedonia to the east, and Serbia and Montenegro to the north. In the west, the country has about 360 km of coastline on the Adriatic Sea. The current population is just above 3.5 million.

Until the 1990s, Albania was run on strict one-party-state lines under the dictator Enver Hoxha, and the country was almost completely isolated from its neighbors and the rest of the world. After the communist period, democracy was introduced, and the country's first elections were held in 1992. In Albania, the largest ethnic and linguistic group are Albanians, and more than 95% of the population speaks some form of Albanian (Albanian, Gheg; Albanian, Tosk) as its first language. Smaller linguistic groups account for the remainder of the population, the largest groups being speakers of Greek, Vlax Romani, and Aromanian (Vlach, Macedo Romanian), each with more than an estimated 50 000 speakers. Macedonian and Serbo-Croatian are spoken by fewer people.

The Albanian spoken in Albania falls into two dialects: Gheg Albanian is spoken in the north and Tosk Albanian, on which Standard Albanian is based, is spoken in the south. Albanian is also spoken outside of Albania, most notably in Macedonia and in the Kosovo province, which is currently under international administration. During the war in Yugoslavia in the late 1990s, about 500 000 Kosovo Albanians took refuge in Albania.

In Albania, the language of the media and broadcasting is Albanian, but the state-owned Albanian Radio and TV programs are supplemented by its external service, Radio Tirana, which runs radio programs in eight languages. In addition, many parts of Albania can pick up Italian and Greek TV stations by means of terrestrial aerials.

Alcover, Antoni Maria (1862–1932)

J Carrera-Sabaté, Universitat de Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Antoni Maria Alcover i Sureda was born in Manacor (Majorca) on February 2, 1862. In 1877, he started studying in the Seminary of Palma de Mallorca. There, he discovered his interest in literature and languages. Beginning in 1880, he collaborated in *L'Ignorancia*, and in 1882 he won his first literary award. In 1886, he took Holy Orders.

Parallel to his priestly work, Alcover was the author of an enormous body of work – apologies, polemics, history, archaeology, and, especially, folklore and linguistics. The most valued manifestations of his folklorist work are his *Contarelles* (1885, 1915) and *Rondayes* or *Rondalles* (from 1896), published under the pseudonym 'Jordi des Recó.' Undoubtedly, the work that became essential to the history of Catalan and Romance lexicography is the *Diccionari català-valencià-balear* (1980), for which the author wrote a public invitation to collaborators (*Lletra de convit*) in 1901 (published in 1902). The scholars' acceptance of this ambitious enterprise transcended the local ambit. This generated the need for a means of communication among the contributors to the dictionary: the *Bolletí del Diccionari de la Llengua Catalana,* the first linguistic journal of the Catalan-speaking areas.

At the same time and until 1928, Alcover took what he called *eixides filològiques*, these being 'philological leaves,' consisting of: (1) training journeys: as a self-taught person, and aware of his limited linguistic knowledge, he visited European countries to learn scientific methodology on dialectological research; and (2) fieldwork journeys around the Catalan-speaking countries, in order to explore the state of Catalan and also to extend his work.

His research incorporated a new approach into Catalan dialectal variation, based on the exploration of speakers' pronunciations. His results were published in the *Bolletí*: *Una mica de dialectologia catalana* (1914–1915) and in *Questions de llengua i literatura catalana* (1902–1903).

In 1911, Alcover was named president of the Catalan Language Institute (*Secció Filològica de l'Institut d'Estudis Catalans*). However, strong differences in character and in working objectives with the institute members made him leave. After this association broke off, the Spanish government subsidized the *Diccionari* from 1920 to 1926. When the subsidy was cut off, Alcover did his utmost to ensure the continuity of the dictionary, and he even went into debt. The dictionary became a reality at the end of 1926. Nowadays it is a useful 10-volume lexical inventory of 160 000 Catalan words obtained from more than 300 localities. It was written first by Alcover and then by Francesc de Borja Moll, and later, with the collaboration of Manuel Sanchis Guarner and Aina Moll. By Alcover's death, on January 8, 1932, the first installment of the second volume of the *Diccionari català-valencià-balear* had been published.

Algeria: Language Situation

F Aitsiselmi, University of Bradford, Bradford, UK

© 2006 Elsevier Ltd. All rights reserved.

This article is a brief presentation of the current linguistic situation in Algeria following the language planning policies implemented by successive Algerian governments since 1962.

Algeria (Al Djazair in Arabic) is situated in Northern Africa, bordering the Mediterranean Sea, between four other nations of the Maghreb: Morocco and Mauritania to the west and Tunisia and Libya to the east. Its 1200 km of northern coastline runs along the Mediterranean Sea, and it stretches some 2000 km south to the borders of Niger and Mali. It is Africa's second largest country, covering an area of 2 381 741 sq km. Two mountain ranges divide Algeria into three geographical zones. In the north is a fertile coastal lowland strip, which has a temperate Mediterranean climate and a high plateau zone, where the vast majority of the population (87%) is concentrated. In the south, the Sahara Desert accounts for four-fifths of the country's territory. It is arid and sparsely populated but contains the fifth largest reserves of natural gas in the world. Algeria is the world's second largest gas exporter. The oil and gas industry is the backbone of the economy, accounting for 95% of export earnings.

Language Conflict

Immediately after achieving independence from France in 1962, Algeria launched a series of measures to re-Arabize the country. This policy, referred to as 'Arabization', was largely a reaction against the cultural and linguistic domination of France. It had three principal objectives. First, it would reverse the dominance of the French language and impose the use of Arabic on all the sectors that used to be the exclusive domain of French – education, law, the media, and the government. Second, it would replace a foreign language (French) by what was seen as the national language (Arabic). Third, Arabization aimed to eliminate all vernaculars, i.e., spoken varieties of Arabic and Tamazight, to ensure national unity around a central government whose working language would be Arabic. All four Algerian constitutions (1963, 1976, 1989, and 1996) reject multiculturalism and multilingualism, stating that Arabic is the sole official and national language.

However, today, Algeria is still a multilingual country where at least three languages are in competition: Arabic, Tamazight, and French.

The Arabic Language

Arabic is a diglossic language whose high variety has been declared constitutionally the national and official language of the country. The term 'Arabic' refers to several language varieties that exist side by side throughout the community, each with a definite functional distribution. These varieties can be divided into three main categories. The first is Classical Arabic, which is the most prestigious variety. It has a long literary tradition and, as the language in which the Koran is written, it is considered to be a model of linguistic excellence.

The second is Modern Standard Arabic or literary Arabic, a form that has evolved from efforts to modernize high Arabic and make it better able to meet the demands of modern life. It is the official language of government, the courts, education, science, and the media. It is also the medium of oral communication used by educated Arab people across nations, with different spoken varieties. Its prestige also stems from the fact that it is recognized as an official language of various international organizations and is used in all the Arab countries, stretching from the Persian Gulf in the east to the Atlantic Ocean in the west.

The third is the low variety, which is also known as Dialectal, Colloquial, or Algerian Arabic. It is spoken by the majority of the population, for whom it is the mother tongue (except for Tamazight speakers). It consists of a number of regional varieties, including rural and urban forms (Algerian Saharan spoken and Algerian spoken), which are not normally used for written communication. The low variety is viewed as a degraded form of pure Arabic and therefore has no official status. Like Tamazight, it is classed under the derogatory category of 'dialects.'

Tamazight

The policy of Arabization met with resistance from the Tamazight-speaking populations, who saw it as a negation of their national cultural heritage. Tamazight, which is the language of the indigenous people (Berbers) of North Africa, is mentioned in none of the country's constitutions.

Statistics concerning the number of Tamazight speakers vary, because Algerian censuses do not take linguistic factors into consideration. They are estimated to make up between 25% and 30% of the total population.

The main Berber varieties are Taqbaylit (Kabyle) spoken in the Northern area of Kabylia, which hosts the largest Berber population. The second biggest language group is Chaouia (Shawiya) in central

eastern areas of Algeria. The third language group can be found in the Saharan areas of the countries and consists of varieties such as Tumzabt, Taznatit, and Tamahaq.

There have also been some moves to recognize the validity of Tamazight. The Haut Commissariat à l'Amazighité (High Commission for Amazighity) was created in 1995 to promote and develop Tamazight, with a view to introducing it in the educational system. Some level of official recognition has been achieved with the broadcast of a news summary on national television and the opening of undergraduate and postgraduate courses in Tamazight linguistics, literature, and culture at the universities of Tizi-Ouzou and Bejaia in the Kabylia region.

In October 2001, after widespread unrest in Kabylia, Tamazight was recognized as Algeria's second national language. Nevertheless, it is still not an **official** language and continues to be a matter of contention in such areas as education. The current government, led by President Bouteflika, has stated that the recognition of Tamazight as an official language would require a change in the constitution – a change they were not about to make.

The French Language

French is Algeria's linguistic inheritance from the colonial period. It has been under attack, and its status as the main foreign language was under threat in the 1990s, when it was in competition not only with Arabic but also with English as the language of access to science, technology, and international business. However, the 2004 reform of the educational system reinstated French as the first foreign language to be taught as a compulsory subject from the second year of the primary education cycle.

The language-planning process in Algeria has resulted in a language shift, with Arabic replacing French to a certain degree in various areas of social life. However, paradoxically, owing to the policy of compulsory education for all, more people nowadays have a working knowledge of French than during the colonial period.

A number of factors reinforce the presence of French in Algerian society. First, a large community of Algerian immigrants (600 000, excluding citizens with dual nationality; or 2 million, counting those with French nationality and members of the second and third generations) lives in France, maintaining strong links with their families and friends in Algeria. As a result of these sociocultural links, France is the most popular destination for Algerian tourists. Furthermore, improved telecommunications and the ready availability of satellite dishes have introduced all the French television channels into Algerian homes.

On the global scene, the country had refused to associate itself with the campaigns to promote the use of French internationally. The francophone movement had previously been dismissed as nothing more than a neocolonial instrument of domination. However, despite the fact that Algeria is not a member of the francophone movement, the current president attended the 1999 and 2004 francophone summits. Following his election in 1999 and his re-election in 2004, President Bouteflika dealt with issues that had hitherto been squashed by major taboos linked to Algerian history, religious practices, and the linguistic reality of the country. He praised the Jewish and Christian heritage of Algeria (Benrabah, 2004, p. 51) and he was eager to re-establish a strong bilateral relationship with France by restoring technical and cultural education (Naylor, 2000, p. 288).

Conclusion

Language planning in Algeria has been extremely controversial, representing as it does an attempt to reconcile authenticity, national identity, and modernization and eliminate any legacy of the country's colonial past. To date, the language policy implemented by Algeria has ignored the other languages used by Algerians on the grounds that they were either a threat to national unity (Tamazight) or a legacy of a colonial past that needed to be eliminated (French).

Algonquian and Ritwan Languages

D H Pentland, University of Manitoba, Winnipeg, MB, Canada

© 2006 Elsevier Ltd. All rights reserved.

More than 30 languages of the Algonquian family were formerly spoken along the east coast of North America from about 34°N (Cape Fear, North Carolina) to about 56°N (Davis Inlet, Labrador), around the upper Great Lakes, and west to the foothills of the Rocky Mountains. They were the first North American languages encountered by French and English explorers; by the end of the 17th century several languages had already been described in detail. Three centuries later, however, two-thirds of the languages are no longer spoken, with only English loanwords such as *moccasin*, *skunk*, and *squaw* to reflect their former existence. The 'Ritwan' languages (Wiyot and Yurok) of California are distantly related. Pilling (1891) provides a nearly exhaustive inventory of the earlier sources; later publications are listed by Pentland and Wolfart (1982), but the only comprehensive bibliography of the most recent literature is in Nichols (1981–).

Classification

The only widely accepted genetic subgroup within the Algonquian family is Eastern Algonquian, consisting of the languages which descended from Proto-Eastern Algonquian (Goddard, 1978b). It includes the languages of the Maritime provinces, southern Quebec, and the northern New England states – Micmac (several dialects), Malecite-Passamaquoddy, Etchemin, Eastern and Western Abnaki (two languages, each with several dialects), and Pocumtuck or 'Loup B' – and those formerly spoken in the Hudson and Delaware River basins of New York, Pennsylvania, and New Jersey – two dialects of Mahican, and the two 'Delaware' languages, Munsee (including the divergent Wappinger dialect) and Unami (three dialects). The languages of southern New England and Long Island – Nipmuck ('Loup A'), Massachusett (Wampanoag), Narragansett, Pequot-Mohegan-Montauk, and Quiripi-Unquachog – and those of the southeastern states – Nanticoke, Conoy (Piscataway), Powhatan (Virginia Algonquian), and Roanoke-Pamlico (Carolina Algonquian) – may also be part of the Eastern subgroup, but since all are extinct, the crucial phonological details depend on interpretations of early written records.

The so-called 'Central' languages were located between Hudson Bay and the Ohio River valley; each shares many features with its neighbors, but there are no ancient subdivisions.

Cree-Montagnais-Naskapi is a dialect chain extending across central Canada from Labrador to Alberta, conventionally subdivided according to the reflex of Proto-Algonquian **l*: Plains Cree (Nêhiyawêwin), the dialect with *y* < **l*, in Alberta and Saskatchewan; three varieties of Woods Cree (with ð) in northern Saskatchewan and Manitoba, one of which probably continues the extinct Missinipi dialect (with *r*; cf. Pentland, 2003); three or more varieties of Swampy Cree (with *n*) in Manitoba and northern Ontario; Moose Cree (with *l*) on the southwest coast of James Bay; and Atikamekw (or Tête de Boule, with *r*), in southwestern Quebec, cut off from the others by a dialect of Ojibwa. In the eastern dialects Proto-Algonquian **k* has palatalized to *č* before front vowels: Eastern Montagnais (Innu-aimun) and Eastern Naskapi (with *n* < **l*), in Labrador and southeastern Quebec; Southern Montagnais (with *l*), at Lac St-Jean, Quebec; and the extinct dialect of Tadoussac, Quebec (with *r*). The several varieties of East Cree and Western Naskapi in northern Quebec (all with *č* < **k* and *y* < **l*) are considered transitional between the eastern and western dialects (MacKenzie, 1980), or as varieties of a Western Montagnais dialect (Pentland, 1978); some East Cree speakers understand Moose Cree, but speakers of the nonpalatalized dialects generally find East Cree and (other) Montagnais dialects completely unintelligible.

Ojibwa (also spelled Ojibway or Ojibwe) is another dialect chain, extending from Quebec to

More than 30 languages of the Algonquian family were formerly spoken along the east coast of North America from about 34°N (Cape Fear, North Carolina) to about 56°N (Davis Inlet, Labrador), around the upper Great Lakes, and west to the foothills of the Rocky Mountains. They were the first North American languages encountered by French and English explorers; by the end of the 17th century several languages had already been described in detail. Three centuries later, however, two-thirds of the languages are no longer spoken, with only English loanwords such as *moccasin*, *skunk*, and *squaw* to reflect their former existence. The 'Ritwan' languages (Wiyot and Yurok) of California are distantly related. Pilling (1891) provides a nearly exhaustive inventory of the earlier sources; later publications are listed by Pentland and Wolfart (1982), but the only comprehensive bibliography of the most recent literature is in Nichols (1981–).

Classification

The only widely accepted genetic subgroup within the Algonquian family is Eastern Algonquian, consisting of the languages which descended from Proto-Eastern Algonquian (Goddard, 1978b). It includes the languages of the Maritime provinces, southern Quebec, and the northern New England states – Micmac (several dialects), Malecite-Passamaquoddy, Etchemin, Eastern and Western Abnaki (two languages, each with several dialects), and Pocumtuck or 'Loup B' – and those formerly spoken in the Hudson and Delaware River basins of New York, Pennsylvania, and New Jersey – two dialects of Mahican, and the two 'Delaware' languages, Munsee (including the divergent Wappinger dialect) and Unami (three dialects). The languages of southern New England and Long Island – Nipmuck ('Loup A'), Massachusett (Wampanoag), Narragansett, Pequot-Mohegan-Montauk, and Quiripi-Unquachog – and those of the southeastern states – Nanticoke, Conoy (Piscataway), Powhatan (Virginia Algonquian), and Roanoke-Pamlico (Carolina Algonquian) – may also be part of the Eastern subgroup, but since all are extinct, the crucial phonological details depend on interpretations of early written records.

The so-called 'Central' languages were located between Hudson Bay and the Ohio River valley; each shares many features with its neighbors, but there are no ancient subdivisions.

Cree-Montagnais-Naskapi is a dialect chain extending across central Canada from Labrador to Alberta, conventionally subdivided according to the reflex of Proto-Algonquian **l*: Plains Cree (Nêhiyawêwin), the dialect with *y* < **l*, in Alberta and Saskatchewan; three varieties of Woods Cree (with ð) in northern Saskatchewan and Manitoba, one of which probably continues the extinct Missinipi dialect (with *r*; cf. Pentland, 2003); three or more varieties of Swampy Cree (with *n*) in Manitoba and northern Ontario; Moose Cree (with *l*) on the southwest coast of James Bay; and Atikamekw (or Tête de Boule, with *r*), in southwestern Quebec, cut off from the others by a dialect of Ojibwa. In the eastern dialects Proto-Algonquian **k* has palatalized to *č* before front vowels: Eastern Montagnais (Innu-aimun) and Eastern Naskapi (with *n* < **l*), in Labrador and southeastern Quebec; Southern Montagnais (with *l*), at Lac St-Jean, Quebec; and the extinct dialect of Tadoussac, Quebec (with *r*). The several varieties of East Cree and Western Naskapi in northern Quebec (all with *č* < **k* and *y* < **l*) are considered transitional between the eastern and western dialects (MacKenzie, 1980), or as varieties of a Western Montagnais dialect (Pentland, 1978); some East Cree speakers understand Moose Cree, but speakers of the nonpalatalized dialects generally find East Cree and (other) Montagnais dialects completely unintelligible.

Ojibwa (also spelled Ojibway or Ojibwe) is another dialect chain, extending from Quebec to

Saskatchewan. The Algonquin dialect of southwestern Quebec is separated by a large number of isoglosses from its immediate neighbors (Rhodes and Todd, 1981), but shares a number of features with Northern (or Severn) Ojibwa, in northwestern Ontario. A quite different dialect, also usually called Algonquin, is spoken at Maniwaki, Quebec; it apparently is the result of a large migration of Eastern Ojibwa speakers from Lake Nipissing into an originally Algonquin-speaking community at Oka. The Eastern Ojibwa dialect of southern Ontario and the Ottawa (or Odawa) dialect of Michigan and southwestern Ontario have both reduced or lost all unstressed vowels. According to Rhodes and Todd (1981), the other dialects are Central Ojibwa, in northeastern Ontario; Northwestern Ojibwa, between Lake Superior and Lake Winnipeg; Southwestern Ojibwa (Chippewa), in northern Michigan, Wisconsin, and Minnesota; and Saulteaux (Plains Ojibwa) in southern Manitoba and eastern Saskatchewan.

Potawatomi, originally spoken in southern Michigan, was once a part of the Ojibwa dialect chain; it separated before Ojibwa merged **ye·* with *i·*, prior to the first contact with Europeans, but shares with some southern Ojibwa dialects the complete loss of unstressed vowels. Menomini (or Menominee), in Wisconsin, has many Ojibwa loanwords and shares some sound changes (including **ye· > i·*), but is in other respects quite different from other Algonquian languages.

Four dialects of a single language were formerly spoken in southern Michigan: Fox (or Mesquakie), Sauk, Kickapoo, and the extinct Mascouten dialect. The three surviving varieties are probably still mutually intelligible, but Kickapoo has some significant differences.

The states of Illinois and Indiana were the home of the Miami-Illinois language, which contained a number of dialects, including Kaskaskia, Peoria, Tamaroa, Wea, Piankashaw, and Miami; by the 1870s there were only two groups, known as Peoria and Miami, but they may not correspond to older dialect divisions. In the early 18th century the Michigamea spoke a dialect of Illinois (cf. Masthay, 2002: 26), but earlier may have spoken an unrelated language (Goddard, 1978a: 587).

The Shawnee originally lived in southern Ohio, but during the historic period they often split into widely scattered bands, eventually merging into three politically independent groups, the Eastern Shawnee, Cherokee Shawnee, and the Absentee Shawnee, all now resident in Oklahoma. Neither early nor recent dialect differences have yet been examined in detail.

In addition to Plains Cree and Plains Ojibwa (Saulteaux), there were at least six other Algonquian languages spoken on the Great Plains (Goddard, 2001). Blackfoot is spoken in Alberta by the Blackfoot (Siksika), Blood, and Northern Peigan, and in Montana by the Southern Peigan (or Blackfeet) with only slight differences. Arapaho (including the extinct Besawunena dialect, in Wyoming and Oklahoma) is closely related to Atsina or Gros Ventre (in Montana). Some Arapaho formerly spoke Ha'anahawunena, an unrecorded language said to have been very different from Arapaho; the Southern Arapaho originally spoke Nawathinehena, a distinct Algonquian language of which only a few words were recorded in 1899.

The two modern Cheyenne communities in Montana and Oklahoma speak almost identical dialects; the Sutaio, who joined the Cheyenne in the 19th century, spoke a different dialect or language, but little reliable information about it was ever recorded.

In 1913 Edward Sapir showed that Wiyot and Yurok, two languages of northwestern California which had just been assigned to a new linguistic family called Ritwan, are related to the Algonquian languages.

Sapir extended the name Algonkin (i.e., Algonquian) to the larger group. This unfortunate relabeling was misunderstood by Truman Michelson, who argued (correctly) that Wiyot and Yurok are not 'Algonquian' in the same sense as Fox or Cree; he was wrong, however, to deny the more distant relationship, which later work has amply confirmed.

The family consisting of the Algonquian languages plus Wiyot and Yurok is now called Algic; the name Ritwan is reserved for Wiyot and Yurok, should it turn out that they form a single branch within the Algic family: the question is still undecided. The last speaker of Wiyot died in 1962; fieldwork continues with the last few speakers of Yurok.

The extinct Beothuk language of Newfoundland may have been related to the Algonquian family, but the early 19th-century vocabularies are poorly transcribed and very inconsistent (Hewson, 1978); some words and inflections appear to be cognate, but others bear no resemblance to their Algonquian counterparts, even allowing for the usual kinds of transcription errors. It is unlikely that the relationship (if there is one) will ever be demonstrated satisfactorily.

Edward Sapir placed Algonquian in a stock with Kutenai and the Salishan, Chimakuan, and Wakashan families, but the similarities he noted are probably ancient loans or areal features. The few resemblances between single morphemes in Proto-Algonquian and the languages of the Gulf coast are probably coincidental.

Demography

No accurate census of Algonquian speakers exists. According to the 2001 Canadian census there were 72 680 Cree people, but 102 185 speakers of the Cree language; Grimes (1992) estimated 42 725 speakers, but even this number may be too high. An additional 14 000 people speak the 'palatalized' dialects, East Cree, Naskapi, and Montagnais.

There are at least 20 890 speakers of Ojibwa in Canada (2001 census) and perhaps 30 000 in all; earlier estimates ranged above 50 000 speakers. About 40–50 fluent speakers of Potawatomi remain, although 200–500 were estimated 30 years ago. A few dozen elderly people still speak Menomini. Perhaps 200 people still speak Fox or Sauk, but Kickapoo has well over 1000 speakers. Shawnee is said to have 200–250 speakers; the Miami-Illinois language became extinct about 50 years ago.

Of the Eastern Algonquian languages, only Micmac and Malecite-Passamaquoddy are still viable. There may be as many as 8000 speakers of Micmac in the Maritime provinces and southern Quebec, and more than 1000 speakers of Malecite-Passamaquoddy in New Brunswick and Maine. The last speaker of Penobscot (Eastern Abenaki) died in 1993; a few elderly people may still speak Western Abnaki. Perhaps a dozen people in southern Ontario speak Munsee Delaware, but Unami, in Oklahoma, is virtually extinct.

The 2001 Canadian census reported 2740 Blackfoot in Canada, but 4495 speakers of the language; there may be 5000 speakers in all, including a few children. Arapaho is estimated to have several hundred fluent speakers (Goddard, 2001), but there are only two speakers of Atsina (Gros Ventre) left. Cheyenne is spoken by about 2500 people.

Since the number of speakers of many Algonquian languages has declined rapidly in recent years, many communities have sought to revitalize their traditional language by introducing language programs in the local schools. A few programs have been very successful, but many others have failed to increase the use of the language outside the classroom.

Recent attempts to revive extinct languages such as Miami-Illinois and Pequot-Mohegan cannot yet be evaluated.

Typological Characteristics

Algonquian languages are polysynthetic, hierarchical, nonconfigurational head-marking languages with discontinuous constituents and relatively free word order.

Phonology

The parent language, Proto-Algonquian (PA), was reconstructed by Leonard Bloomfield (1925, 1946), in part to demonstrate that the comparative method can be applied successfully to 'unwritten' languages as well as those with ancient records. PA probably had 13 consonants (*p, t, k, k^w, s, $š$, h, θ, l, m, n, w, y) and four short and four long vowels (*a, e, i, o; *$a{\cdot}$, $e{\cdot}$, $i{\cdot}$, $o{\cdot}$). Bloomfield also reconstructed *$č$, but it occurs only before *$i(\cdot)$ and *y (where it does not contrast with *t); however, *$č$ may also have replaced *t in words with diminutive consonant symbolism. He did not reconstruct *k^w, but it probably contrasted with the sequence *kw. Consonant clusters could not occur word initially, and every word ended in a vowel (usually, but not always, a short vowel).

In PA, stress was predictable, with all long vowels and every second short vowel receiving a stress; this stress system is preserved with little change in Ojibwa, and underlies the vowel length alternations in Menomini, but some languages (e.g., Plains Cree, Montagnais) have replaced it with systems which count syllables from the end of the word, and Miami-Illinois reflects both types. Arapaho-Atsina and Cheyenne have developed pitch accent systems (largely from the old length contrast), while others (Eastern Montagnais, Kickapoo, and Malecite-Passamaquoddy) have acquired pitch contrasts from the loss or contraction of certain syllables.

Almost all the daughter languages have merged PA *θ and *l, and some have a further merger with *n (as in Massachusett and in modern Ojibwa, Menomini, and Fox) or with *y (as in Pequot-Mohegan); although the PA phonetic values of the consonants Bloomfield labeled *θ and *l are debated, the reflexes in Table 1 clearly show that they were distinct phonemes in PA. In morpheme-final position, *t and *θ still contrast in Cree, and *θ and *l still contrast in Shawnee.

Inflectional Morphology

Nouns are classified as animate (NA) or inanimate (NI), the animate category including not only all

Table 1 Intervocalic reflexes of five Proto-Algonquian consonants in selected languages

	*t	θ	n	l	y
Plains Cree	t	t	n	y	y
Swampy Cree	t	t	n	n	y
Ojibwa, Fox	t	n	n	n	y
Shawnee	t	l	n	l	y
Pequot-Mohegan	t	y	n	y	y
Arapaho	t	θ	n	n	n

living things but also some plants and their products, a few body parts, and miscellaneous other items such as snow, kettles, and snowshoes; all other nominals, including most body parts and the personal pronouns, are grammatically inanimate.

Possession is indicated by a pronominal prefix; plurality of the possessor is marked by a suffix. Most kinship terms and body parts, and a very few other noun stems, are 'dependent' (inalienably possessed); a special 'unspecified possessor' prefix is used with body part nouns when there is no actual possessor (e.g., **me-sit-i* 'someone's foot'), but to express 'a daughter' Algonquian languages must resort to a verbal derivative, literally '(one that) someone has as a daughter.'

Nominals are obligatorily specified as singular (PA **-a* NA, **-i* NI) or plural (PA **-aki* NA, **-ali* NI), but with the loss of final vowels singulars have no overt marking in most of the daughter languages. The third person distinguishes between proximate (central, in focus) and obviative, but only animate nouns have separate obviative inflections (PA **-ali* obv. sg., **-ahi* obv. pl.); otherwise, obviation is evident only in verb agreement. Some languages have a second set of endings to indicate inaccessibility or absence (PA **-a·* NA sg., **-e·* NI sg., etc.).

The vocative has distinct singular and plural suffixes. A locative (in **-[e]nki*) may be derived from any possessed or unpossessed noun stem (as well as a few other initial elements), but it is an uninflected 'particle' which does not distinguish number or obviation.

Intransitive verbs have distinct stems for animate and inanimate subjects, transitive verbs for animate and inanimate objects: e.g., Cree *kisiso-* 'be hot (ANIM)', *kisite-* 'be hot (INAN)', *kisisw-* 'heat (ANIM)', *kisisam-* 'heat INAN'. Animate intransitive (AI), inanimate intransitive (II), and transitive inanimate (TI) stems have similar inflections; transitive animate (TA) stems have more complicated paradigms, since they may distinguish almost any combination of subject and (animate) object.

Verb inflections are divided into three formally distinct sets of paradigms ('orders'). The PA forms of the basic endings were reconstructed by Bloomfield (1946); Goddard (1979) provided much additional information.

The independent order, used primarily in main clauses, employs the same personal prefixes as possessed nouns, to indicate the highest-ranking argument of the verb (as determined by the hierarchy 2nd person > 1st > unspecified > anim. 3rd > anim. obv. 3rd > inan. 3rd > inan. obv. 3rd) if this is not otherwise marked; suffixes indicate direction (direct when the agent of a TA verb outranks the patient, inverse when the agent is not the highest-ranking argument), plurality and obviation, negation, and various modal categories (Pentland, 1999).

The conjunct and imperative orders employ only suffixes to indicate the same categories, but some forms in the conjunct order (such as participles) also have 'initial change' or ablaut of the vowel of the first syllable of the verb complex (Costa, 1996).

Derivational Morphology

Most Algonquian words can be described as consisting of an initial, an optional medial, and a final, each of which may itself be derived from shorter elements (Goddard, 1990). Roots (unanalyzable initials) are typically adjectival or adverbial rather than nominal or verbal, e.g. **melw-* 'good, well' (as in **melwa·kamyi-* II 'be good water, taste good [of a liquid]', **melwa·pam-* TA 'like to look at someone', **melwenkʷa·m-*AI 'sleep well') and **wel-*'properly arranged' (as in **welenam-* TI 'arrange something by hand, place something in readiness', **welešam-* TI 'cut something to shape'). The final determines the word class; thus beside the TI stem **welešam-* (with final **-[e]šam-* 'cut-INAN') there is a corresponding TA stem **welešw-* 'cut someone to shape' (with **-(e)šw-* 'cut-ANIM'), and further derivatives **welesamaw-* TA 'cut something to shape for someone' (with benefactive final **-aw-*), **welešama·swi-* AI 'cut something to shape for oneself' (with reflexive final **-[e]swi-*added to the benefactive), and **welešama·sowen-* NI '(act of) cutting something to shape for oneself' (with noun-final **-wen-* added to the reflexive). The addition of an additional final almost always changes the word class.

Medials are nominal elements incorporated between the initial and final. Some are classifiers, such as **-a·xkʷ-* 'wooden', **-a·peθk-* 'stone or metal', and **-a·pye·k-* 'stringlike', in the II stems **kenwa·xkʷat-* 'be long [of something wooden]', **kenwa·peθkat-* 'be long [of a stone or metal object]' and **kenwa·pye·kat-* 'be long [of something stringlike]'. Others correspond to the direct object of the English equivalent, such as **-neθk-* 'hand, arm' in **kenwineθke·-* AI 'have a long hand or arm' or **-eθkʷe·w-* 'woman' in **nɔ·teθkʷe·we·-* AI 'pursue women', but noun incorporation is not very productive and does not interact with agreement.

Syntax

As many as four noun phrases may occur in a single clause, but no more than two arguments can be marked on the verb by inflectional affixes (Thomason, 2004). All verbs obligatorily take a subject, and may take an instrumental argument. TA

stems obligatorily take an animate object; both AI and TI stems may also take an animate object, and TA stems may take a second object. Instrumentals, AI objects, and TA second objects may be of either gender.

Word order is very free: almost all permutations of constituents are grammatical. A noun phrase may be discontinuous, with part before the verb and the remainder after (Reinholtz, 1999); in Fox, compound verbs may also be discontinuous, with other parts of a clause inserted between a preverb and the remainder of the verb complex, as in (1):

(1) ne-kehkeˑnem-ekw-a ni·na eˑh = pwaˑwi-
1ST-know-INV-3RD.ANIM.SG I COMP = not-
keˑkoˑhi -ašeno-ni-ki
something be.absent-OBV-3RD.INAN.SG
'he knows that as for me, nothing is missing'
(Dahlstrom, 1995: 9)

The topic of the subordinate clause, *ni·na* 'I', has been raised to the left-hand edge of the clause; the subject of the II verb *ašeno-* 'be absent' has been moved into the verb complex following the complementizer clitic *eˑh* (which bears the 'initial change') and a negative preverb.

In example (1) the topic has also been copied as the direct object of the matrix verb, which is therefore the TA stem *kehkeˑnem-* 'know someone' rather than TI *kehkeˑnetam-* 'know something'; subjects and (some) objects can also be copied, and the verb of the subordinate clause may be incorporated into the matrix verb, as in the Fox example in (2):

(2) ke-kiˑši = meko yoˑwe
2ND-already = EMPH in.the.past
nepow-eˑnem-ene-pena
die-think-2ND.OBJ-1ST.PL
'we had thought you were already dead'
(Goddard, 1988: 71)

The preverb of the incorporated clause *kiˑši-nep-*'have already died' has been moved to the preverb position of the matrix clause (where it is followed by an emphatic clitic and an adverb) but semantically still modifies only the lower verb.

Mixed Languages

Blackfoot may be descended from a precontact creole: it has (for the most part) normal Algonquian morphology and cognates of many individual morphemes, but few complete words are reconstructible.

A number of pidgins arose during the contact period, based on Powhatan (Virginia, early 17th century), Unami (New Jersey, 17th century), Cree (Hudson Bay, 18th century), and Ojibwa (Lake Superior, 19th century). An early Micmac–Basque pidgin in Nova Scotia was the source of a few Basque loanwords in modern Micmac, such as *elekeˑwit* '(one who is) king' < Basque *errege*.

Métchif or Michif, a French-Cree mixed language, is still spoken in some Metis communities in North Dakota, Manitoba, Saskatchewan, and Alberta (Bakker, 1997), and a remarkably similar French-Montagnais mixed language has developed at Betsiamites, Quebec. In these languages, the noun phrase is mainly French lexical items with French phonology and morphology, while the remainder of the clause is Plains Cree or Southern Montagnais.

Philology and Documentation

With more than four centuries of records on various languages available, philological studies have long played a role in Algonquian linguistics. The earlier English sources have been utilized by many scholars, notably in a study of the historical phonology of Powhatan (Siebert, 1975). The early French records have not been as thoroughly studied, but editions of older grammars (e.g., Daviault, 1994) and dictionaries (e.g., Masthay, 2002) have increased interest in the use of older materials to elucidate various details in the development of the modern languages.

One problem with the early sources is that they tend to provide individual words and partial paradigms rather than connected sentences; most early textual material is based on European originals, and was probably translated by the missionaries themselves. One notable exception is the collection of Massachusett documents edited by Goddard and Bragdon (1988). Since the beginning of the 20th century many texts written or dictated by native speakers have been published, but many more remain in manuscript.

Grammars and dictionaries of many Algonquian languages have been published, but much remains to be done: syntax is seldom treated at length, and some of the dictionaries are pitifully small. Leonard Bloomfield showed the way with a grammar (1962) and an 11 000-word dictionary (1975) of Menomini; notable later productions are the Montagnais-French dictionary compiled by Lynn Drapeau (1991), with nearly 24 000 entries, and the 1100-page reference grammar of Ojibwa by J. Randolph Valentine (2001). Mithun (1999: 328–337) provides a brief survey of the sources available for each of the languages.

Alonso, Amado (1896–1952)

R Cavaliere, Universidade Federal Fluminense, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Internationally known as a great linguist and literary critic of the 20th century, Amado Alonso García was born in Lerin, Spain on September 13, 1896. Alonso's published works in Europe, South America, and in the United States, include his excellent studies regarding Spanish grammar, Romanic linguistics, linguistic theory, language politics, and several essays on literary language. Alonso developed his basic studies in Pamplona (1911–1914) and later managed to follow the courses of Philosophy and Letters (1914–1918). In 1917, Alonso entered as an undergraduate the Historical Studies Center in Madrid, Spain where he studied phonetics with Navarro Tomás.

During the years 1922–1924, Alonso while in Germany, decided to introduce his phonetic studies with University of Hamburg Professor Panconcelli-Calzia. Alonso's first texts treat the Basco dialects sibilant consonants' problem and some varieties of *r* and *rr* in American Spanish. At the end of 1924, Amado Alonso returned to Madrid to work as a teacher at the Historical Studies Center. In 1927, Alonso moved to Buenos Aires, Argentina as he was designated by D. Ramón Menéndez Pidal (*see* **Menéndez Pidal, Ramón (1869–1968)**) to assume the directive chair at the University Philology Institute. Alonso's identification with the great South American nation was very close, and in 1939 he adopted Argentine nationality. Alonso worked as a visiting professor at several foreign universities including the University of Puerto Rico (1927), University of Chile (1936–1941), and at the University of Chicago (1942) where he was honored with a Ph.D. in the Humanities.

Alonso decided to remain permanently in the United States after being invited in 1946 to teach Spanish language and literature at Harvard University located in Cambridge, Massachusetts. While teaching at Harvard, he answered for the Smith Catedra until his death on May 16, 1952 in the United States in Arlington, Massachusetts.

Altaic Languages

L Johanson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

A common designation for the typologically related languages of the Turkic, Mongolic, and Tungusic families is 'Altaic languages'; according to some scholars, this designation also includes Korean and Japanese. The common typological features of these languages include an agglutinative and exclusively suffixing word structure, sound harmony, verb-final word order, with dependents preceding their head, and use of numerous nonfinite verb constructions.

Altaic as 'Ural-Altaic'

The term 'Altaic' was first used by M. A. Castrén in the middle of the 19th century for a supposed family comprising Finno-Ugric, Samoyedic, Turkic, Mongolic, and Tungusic. This group of languages was later called 'Ural-Altaic.' The Ural-Altaic hypothesis, which was largely based on general typological criteria such as agglutination and vowel harmony, was widely accepted in the 19th century. Later on, this hypothesis was seriously doubted. The works on 'Altaic' languages by W. Schott, M. A. Castrén, J. Grunzel, H. Winkler, and others contain abundant incorrect data. Castrén, however, rejected the purely typological approach and applied linguistic criteria of lexical and morphological comparison. There are not sufficient materials to establish a Ural-Altaic protolanguage.

Scholars of the following period, e.g., J. Németh and J. Deny, who took a more cautious attitude, published detailed works on phonology, word formation, etc. Syntactic typological arguments for the unity of Ural-Altaic were, however, discussed as late as 1962, by Fokos-Fuchs.

Altaic as 'Micro-Altaic'

Scholars such as G. J. Ramstedt and N. Poppe argued for a 'Micro-Altaic' family (Comrie, 1981: 39) that at least consisted of Turkic, Mongolic, and Tungusic, three well-established genealogical groups. Ramstedt is the founder of Altaic linguistics in a scientific sense, though his works contain many problematic details. His introduction to Altaic linguistics was published posthumously (1952–1957). Poppe's contributions to Altaic linguistics are not less important. His comparative phonology, planned as the first part of a comparative grammar, appeared in 1960. An example of phonological correspondences according to Ramstedt and Poppe is the supposed development of the initial Altaic stop **p-* into Korean *p-* and *ph-*, into Tungusic *p-* (Nanai), *f-* (Manchu), and *h-* (Evenki), into Mongolic **p-* (Proto-Mongolic), *h-* (Middle Mongolian), *f-* (Monguor), and Ø- (Buriat, Oirat, Kalmyk, etc.), and into Turkic *h-* (Proto-Turkic, some modern languages) and Ø- (most modern languages). Ramstedt's and Poppe's arguments were largely accepted until they were challenged by G. Clauson (1956, 1962). Opponents such as J. Benzing and G. Doerfer expressed doubts even against this Micro-Altaic unit as a valid genealogical family.

Whereas the Altaicists regarded certain similar features as a common heritage from a protolanguage, others claimed that the similarities were the result of contact processes. Thus certain common features in Mongolic and Chuvash could go back to Proto-Altaic or had been borrowed into Mongolic from a language of the Chuvash type. Clauson had criticized the lack of evidence for a common basic vocabulary in Altaic. In his huge work on Turkic and Mongolic loanwords in Iranian, Doerfer (1963–1975) refuted the Altaic etymologies presented by Ramstedt, Poppe, and others, arguing that similarities that can be attributed to general typological principles or to areal diffusion must be excluded from genealogical comparisons.

A possible Altaic unity must have been dissolved about 3000 B.C. The crucial question in Altaic comparative studies is by which methods common elements due to early contacts can be distinguished from elements inherited from a protolanguage. One problem is the scarcity of early data. Whereas Indo-European is attested already in the second millenium B.C., there are no real Turkic sources prior to the 8th century (East Old Turkic inscriptions in the Orkhon valley, Inner Asia). The first Mongolic materials are found in *The secret history of the Mongols* (believed to be written around 1240 A.D., partly based on older materials). The first substantial materials documenting Tungusic emerge centuries later.

The Turkic–Mongolic–Tungusic Relationship

As for the relationship between Turkic and Mongolic, it has been possible to establish a number of convincing sound laws on the basis of words with similar sound shape and content, and to find certain corresponding derivational and grammatical suffixes. The question is how to judge these similarities. The earliest Turkic and Mongolic sources hardly show any common features except for intercultural words such as *qaγan* 'supreme ruler' and *teŋri* 'heaven.' Middle Mongolian displays a number of words

with similar Turkic equivalents. The few pairs of corresponding words do not, however, relate to the most significant parts of the vocabulary, i.e., numerals, kinship terms, and basic verbs, nouns, and adjectives. A few common elements are found in morphology. On the other hand, it is obvious that later Mongolic languages have converged with Turkic by giving up some old features, e.g., an inclusive vs. exclusive distinction in pronouns and verbs, grammatical gender in verb forms, agreement between the adjectival attribute and its head, and the option of postposed adjectival attributes.

Many similarities may thus be due to contact processes. There were close ties between Turkic and Mongolic as early as the middle of the first millennium B.C. Borrowings in both directions had taken place since early times. With the rise of the Chingisid Empire in the 13th century, many Turkic varieties came under strong Mongolic influence. The impact lasted longer in areas of intensive contact, such as South Siberia and the Kazakh steppes. The lexical influence is particularly strong in Tuvan, Khakas, Altay Turkic, Kirghiz, Kazakh, etc. Look-alikes that occur only in typical contact zones cannot easily be used as evidence for genealogical relatedness.

Mongolic displays early layers of loanwords from several Turkic languages and has developed many structural traits under Turkic influence. Words common to Turkic and Mongolic, e.g., Bulgar-Mongolic correspondences, are regarded by Altaicists as true cognates and by non-Altaicists as Turkic loans in Mongolic. Some scholars consider the possibility that correspondences between Turkic and Mongolic go back to a common adstrate, some 'language X' that might have delivered loans to both groups. Tungusic words considered by Altaicists as Altaic are rather regarded by non-Altaicists as loans from Mongolic in certain contact areas. Similar derivational and grammatical suffixes are very scarce. Mongolic and Tungusic had been in contact for a long time prior to the first documentation of Tungusic. Except for recent Yakut loans in North Tungusic, there are hardly any plausible lexical correspondences between Turkic and Tungusic. In a non-Altaicist perspective, the overall Turkic–Mongolic–Tungusic relationship thus appears to be due to diffusion rather than to genealogical relatedness. According to this view, words common to all groups may have wandered along the path Turkic → Mongolic → Tungusic.

After decades of discussions, the nature of the relationship between the Altaic languages is still controversial. Many common features are the result of recent contact, often limited to certain languages within the groups. The question is what reliable correspondences remain to justify the recognition of Altaic as a family in the sense of Indo-European or Semitic. There is no consensus as to whether the relatedness is proven, still unproven, or impossible. Some scholars argue that too few features are common to all three groups, and only to these groups. There are clear lexical and morphological parallels between Turkic and Mongolic, and between Mongolic and Tungusic, but not between Turkic and Tungusic. All three groups exhibit a few similar features, e.g., in the forms of personal pronouns, but similarities of this kind are found in different unrelated languages, in the rest of northern Eurasia and elsewhere. Today, however, compared to the 1960s, the fronts between Altaicists and non-Altaicists are not always as rigid. For example, the pronounced non-Altaicist Doerfer, who had criticized the proposed Altaic sound laws as being construed less strictly or even *ad hoc*, has accepted the above-mentioned development of **p-* into Turkic *h-* and Ø-: e.g., **pat* 'horse,' *hat* (Khalaj, etc.), *at* (most Turkic languages). Doerfer expresses his appreciation of the achievements of the Altaicist Ramstedt in the following way: "We must be grateful to the ingenious founder of Altaistics as a science for discovering so many sound laws which are valid to this date" (Doerfer, 1985: 135).

Korean and Japanese

The most controversial point in recent discussions has been whether Korean and Japanese (with the closely related Ryukyuan language) should be regarded as members of an Altaic family. G. J. Ramstedt (1939, 1949) was the first scholar to attempt to prove a remote relationship beween Turkic–Mongolic–Tungusic and Korean. Though his comparisons have been heavily criticized in more recent studies, N. Poppe considered Ramstedt to have identified at least 150 incontestable Korean–Tungusic–Mongolic–Turkic cognates.

Japanese has often been taken to consist of an Austronesian substratum and an Altaic superstratum. E. D. Polivanov (1924) argued that it is of hybrid origin, containing both Austronesian elements and continental elements that are also found in Korean and Micro-Altaic. In an early study, Ramstedt (1924) investigated possible links between Japanese and Altaic without reaching a clear final conclusion. Forty-two years later, S. E. Martin (1966) provided 320 etymologies relating Japanese to Korean on the basis of regular sound correspondences, which allowed him to reconstruct Proto-Korean–Japanese forms. R. A. Miller (1971), who established a set of sound correspondences to the Proto-Altaic phonemes reconstructed by Poppe (1960), clearly claimed

Japanese to be one branch of the Altaic family. K. H. Menges (1975) took up a number of Miller's arguments and elaborated further on them. In his book on the Altaic problem and the origin of Japanese (1991), S. A. Starostin established sound correspondences between Japanese, Korean, and Altaic on the basis of numerous lexical comparisons of Turkic, Mongolic, Tungusic, Korean, and Japanese lexical items. J. Janhunen (1992, 1994), however, pointed out some problems with the Altaic affiliation of Japanese, which he considers premature. He takes Japanese and Ryukyuan to form a distinct family of its own and the Old Koguryŏ language, once spoken on the Korean peninsula, to be a close relative of Japanese.

Alvar, Manuel (b. 1923)

M C Augusto, University of Utrecht, Utrecht, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

In the 20th century, Spanish linguistics, or more precisely, the philology, was dominated by two great scholars: Ramón Menéndez Pidal in the first half and Manuel Alvar (López) in the latter half.

Between his birth on July 8, 1923 in Benicarló (Castellón) and his death in Madrid on the August 13, 2001, Manuel Alvar had a brilliant academic career, which got off to a swift start. One year after he finished his degree in romance philology at the University of Salamanca (1945), he received his Ph.D. from the University of Madrid, and in 1948, still only in his mid-20s, he became the Chair of Historical Grammar of the Spanish Language at the University of Granada. From then on he was an enthusiastic teacher and a prolific researcher, who taught in every Spanish university and in almost all of the universities on the South American continent. As a visiting professor he worked in more than 15 universities outside the Spanish-speaking world; in Albany (NY) he taught until 1998. He created several courses on Spanish philology, among them the famous *Curso Superior de Filología de Málaga*, which, from 1966 to 1997, was given every summer for 6 weeks. In 1975 he joined the Real Academia Española, which he directed from 1989 to 1991.

During his long academic career Alvar supervised about 250 Ph.D. dissertations, and over 850 titles can be found in the list of his publications, excluding his contributions to some newspapers, some of them on a regular basis. Also among his publications are 10 books of poetry. The quantity and diversity of his publications illustrate what a diligent and indefatigable academic he came to be. His studies cover an enormous variety of subjects such as phonetics, sociolinguistics, toponymy, history of the language, etymology, medieval literature, and folk poetry. He gathered hundreds of linguistic materials, rescued many examples of Sephardim poetry, and wrote on Sephardim language and literature and on many other philological issues. However, the field in which he distinguished himself the most as a researcher was dialectology, more precisely, geographical linguistics along the academic lines of Karl Jaberg. Without exaggeration it can be said that Manuel Alvar was the foremost Spanish dialectologist of the 20th century and a world expert on Spanish linguistics. His work is widely recognized, which is attested to by the many chairs, institutes, and literary prizes named after him, for example, the Cátedra de Lingüística Manuel Alvar (Universidad Zaragoza, 1985), the Instituto de Investigaciones Lingüísticas y Filológicas 'Manuel Alvar' (Universidad Nacional de San Juan, Argentina, 1992), and the Premio Manuel Alvar Humanidades by the Fundación José Manuel Lara of Sevilla. More than 25 universities from all over the world bestowed on him the title of Doctor Honoris Causa.

Alvar's principal achievement concerning dialectology was indubitably the coordination and elaboration of linguistic atlases of certain regions of Spain and of some countries of South America. The first was the atlas of Andalusia (1962, 6 volumes), and the one with the broadest geographical scope was the *Léxico de los marineros peninsulares* (LMP, 4 volumes, 1985–1988). He wrote detailed studies on other Spanish varieties, such as Aragonese, Andalusian, as well as different South American varieties. His study *El Español hablado en Tenerife* (1955) has a pioneering character and earned him the *Premio Antonio de Nebrija*. Later on this work was complemented by another study, this time about the Canaries dialect spoken in Louisiana.

Typically, Alvar's atlases have a strong ethnographic character. They incorporate, alongside the linguistic features of the language, the mental, social, cultural, and religious dimensions of the speaker, thus giving a detailed cartographical synthesis of the most striking aspects that characterize life in a specific region in all its facets. In this elaboration of the atlases, stressing the relation between the word and the referent it names, he followed closely the theoretical principles laid out by Karl Jaberg and Jacob Jud, as well as the method of Wörter and Sachen. Accordingly, the material is not presented in alphabetical order, but instead refers to notional and semantic fields such as agriculture and connected industries, vegetables, wild animals, stockbreeding, cattle industries, domestic animals, apiculture, the weather and topography, the human body, from the cradle to the grave, popular beliefs and superstitions, religion, games and hobbies, and clothing.

The published results are almost all based on the meticulous fieldwork accomplished by a team, supervised by Alvar's typical determination, and guided by his thorough and personal knowledge of the most distant Spanish-speaking villages in Spain or South America. The density of the number of enquiries per region in his atlases is very high, considerably surpassing the other linguistic atlases produced before his day. In total he supervised six atlases in Spain, five

on Spanish regions and one on the sailors of the Iberian Peninsula. He also had planned two of a more general nature: one on the region of Murcia and one with a peninsular scope, including all the languages of the Iberian region, which would be called *Atlas Lingüístico de España y Portugal*. In South America he intended to elaborate the *Atlas Lingüístico de América,* a major project to which he would contribute studies already published, *El Español en Venezuela: estudios, mapas textos* (2001) and *El Español en el sur de Estados Unidos: estudios, encuestas, textos* (2000). His last book, *Español de dos mundos,* published posthumously, testifies to his keen interest in and great liking for American Spanish.

The work of Manuel Alvar was deeply rooted in his own cultural background and his ardent love for the Spanish cultural heritage in all its aspects and geographical manifestations. Leafing through the hundreds of pages of the atlases he published, we discover the human face of linguistics, how people speak and think, and the intricate bond that exists between language and culture.

American Lexicography

The Beginnings: Noah Webster

Before and for some decades after the American Revolution, British dictionaries (particularly that of Samuel Johnson) were used in the United States, usually in pirated form. The first dictionary produced by an American was *A school dictionary* (1798) by Samuel Johnson, Jr. (not related to the great English lexicographer). This dictionary was short and had only brief (and often flawed) definitions that were considered appropriate for students. Its pronunciation system was inadequate even by the standards of the time (as Johnson himself acknowledged), and it included no Americanisms. About all that can be said for it is that it existed, as the first natively produced dictionary in the United States. The pirated British dictionaries were sometimes better, but their coverage of American English was haphazard. They had occasional but irregular American spelling variants but few genuinely American terms. American English was not recognized as a separate regional standard of English. All this changed with Noah Webster (1758–1843).

Noah Webster began his lexicographic career in 1783 with the publication of the *American spelling book*, also known as *The blue-backed spelling book*. This phenomenally popular work went through many editions and hundreds of printings during Webster's lifetime, and by the end of the 19th century it had sold an estimated 100 million copies. Webster's efforts to combat piracy had an influence on the establishment of federal copyright laws in 1790. In contrast to the exclusively religious leanings of earlier works, the *Spelling book* was marked by a strong patriotic and moral tenor: "A good child will not lie, swear, nor steal," went a typical reading passage, "He will be good at home, and ask to read his book; when he gets up he will wash his hands and face clean." Its spellings adhered to a British model, but in subsequent works Webster changed his mind and argued in favor of spelling reform. He thought deeply about spelling throughout his life, and in mid-life he advocated more radical reforms than those that he eventually adopted in his major dictionaries.

Webster's first dictionary was *A compendious dictionary of the English language* (1806). Less important than his later works, it nonetheless included

several innovations. It was based on John Entick's *Spelling dictionary* of 1764, which had been published in London. Webster added several thousand new entries (many of them Americanisms), explicitly showed inflected forms for strong verbs, and included several encyclopedic appendixes listing, for example, international currencies and U.S. populations and exports. The *Compendious dictionary* adopted a moderately American view of orthography. In it, Webster rejected some of the more radical reforms he had advocated in previous works (after *The blue-backed spelling book*), such as *bred* and *tuf* for *bread* and *tough* (both spellings originally promoted by Benjamin Franklin). But it did include a variety of spelling changes that now mark American spelling as distinct from British: for example, *-er* endings for *theater* and *meter*, and *-or* in *honor* and *favor*. He also adopted spelling reforms that had already been accepted by other lexicographers (British and American), such as the simplification of terminal *-ck* to *-c* in words such as *music* and *logic* and of *-que* to *-k* in *mask* and *check*.

It was with his 1828 *American dictionary of the English language* that Webster truly made his mark. Published in two volumes, it included about 70 000 entries, much larger than other dictionaries of the time. It contains many scientific and technical terms that were not in any other contemporary dictionary, as well as many terms unique to American English, such as *caucus, wampum, tomahawk,* and *skunk*.

Webster devoted particular attention to etymologies. One of his major aims, expressed in his 1810 *Prospectus of a new and complete dictionary of the English language*, was "to deduce words from their primitive roots . . . This part of the work will be new, and will offer results singularly novel and interesting." After some preliminary work, he realized his knowledge was unsatisfactory, so he put aside the project to spend years studying other languages. Unfortunately, his prejudices were too strong to allow him to accept any opposing theories, and his etymologies as a result were too often speculative and (we now know) incorrect. The findings of Jakob Grimm and other European scholars, who at this time were devoting their energies to the comparative method in historical linguistics, were only just becoming known in America; Webster had the misfortune of timing to prevent him from appreciating the importance of their work, as well as an obstinacy of spirit that prevented him from recognizing those revelations he could have accepted. Webster preferred to believe that English words were derived from 'Chaldee' and promoted this view with many fanciful speculations.

The American patriotism that Webster had demonstrated in his earlier writings continued in the 1828 dictionary, with further refinements to the spelling system and additional American entries, as well as new senses for British words that had mutated in America. He defined plantation as "a cultivated estate; a farm" and added a long discursive explanation and discussion of regional usage of the term in different parts of America. Webster stressed the importance of a specifically American dictionary in his Preface: "It is not only important, but, in a degree necessary, that the people of this country, should have an *American dictionary* of the English Language; for, although the body of the language is the same as in England, and it is desirable to perpetuate that sameness, yet some differences must exist."

He chose illustrative quotations from prominent American authors, although he included relatively few, believing them to be an unnecessary luxury. In cases where he felt that an example was necessary, he also felt free to invent one. In this, he differed from Samuel Johnson, all of whose examples are citations from literature and who believed that "the solution of all difficulties, and the supply of all defects, must be sought in the examples." While the number of new Americanisms in Webster's 1828 dictionary was in fact smaller than implied by his rhetoric in the preface, his insistence on the distinctiveness of American English was justified by a myriad of details in the entries. For pronunciations, Webster used his own New England dialect, which he regarded as pure, believing that all other dialects were simply wrong.

Webster's definitions were particularly good; James Murray in 1900 called him "a born definer of words," and more recent critics have praised his "brilliance," "clearness," and "soundness." Where Johnson was terse, Webster was relatively full, and not just by adding needless encyclopedic bulk. For example, Johnson's entire definition of *laboratory* says only "a chymist's workroom." Webster's definition begins with "1. A house or place where operations and experiments in chimistry [*sic*], pharmacy, pyrotechny, &c., are performed" and continues with two additional senses. For *label,* Johnson provided a succinct but vague definition: "1. A small slip or scrap of writing," while Webster gave "1. A narrow slip of silk, paper or parchment, containing a name or title, and affixed to any thing, denoting its contents. Such are the *labels* affixed to the vessels of an apothecary." (The *Oxford English dictionary* [OED] shows this sense to have arisen the 17th century, with quotations from Dryden and Defoe's *Moll Flanders*, among others; so it was not obscure.)

Though Webster was critical of much in Johnson's dictionary, he also used it heavily as a source. Many of his definitions and sense divisions were close or exact copies of Johnson. Webster acknowledged as much in his Preface: "When his definitions are

correct and his arrangement judicious, it seems to be expedient to follow him."

The *American dictionary* was viewed by some people as overly innovative, with many educated Americans being relatively conservative and unwilling to challenge the authority of Johnson. However, in the course of the 19th century, it gradually established itself as the standard work of American lexicography and was the foundation for several revised editions (most recently in 1961) and derivatives.

The 'Dictionary War' of the Mid-19th Century

Only two years after the publication of Webster's *American dictionary,* Joseph E. Worcester published a *Comprehensive pronouncing and explanatory dictionary* (1830), a much smaller and more practical dictionary of about 40 000 entries.

Worcester had been one of Webster's assistants, and under the direction of Webster's son-in-law Chauncey A. Goodrich had produced a revised version of the *American dictionary.* Webster himself disapproved of the changes in this revision, and Worcester published his *Comprehensive dictionary* under his own name only one year after his work on revising Webster's work. Webster accused Worcester of plagiarism, but it must be said that the resemblance is no more striking than the usual similarities between dictionaries with similar goals defining the same language.

Worcester's next major work was the *Universal and critical dictionary of the English language* (1846). Coming not long after a major revision of Webster's *American dictionary* in 1841, it intensified an already virulent publicity battle between their respective publishers, who outdid each other in their accusations, exaggerated press releases, and none-too-scrupulous business practices. Worcester's dictionary had a considerably better pronunciation system, better etymologies, and a scholarly treatment of English grammar and the history of English lexicography. It was generally preferred by conservatives who favored the British standards of usage and spelling that Worcester's book reflected. In 1860 Worcester published his *Dictionary of the English language,* which included more than 104 000 entries. Among its features were thousands of lists and discussions of synonyms, etymologies for given names, and illustrations. It was generally recognized as an excellent dictionary. However, in 1864, a new edition of Webster's dictionary was published, edited by Noah Porter (later the president of Yale University). Its etymologies were revised and vastly improved by the German scholar C. A. F. Mahn. In many ways it adopted the more staid, scholarly treatment characteristic of Worcester; as Landau (2001) observed, "It ended the war of the dictionaries, ironically by abandoning everything characteristic of Webster and adopting Worcester's virtues."

The Century Dictionary

The *Century Dictionary,* first published in six volumes from 1889 to 1891, is generally regarded as one of the great achievements in American lexicography. It was based on Charles Annandale's 1882 revision of John Ogilvie's four-volume *Imperial dictionary* of 1850 (itself based on Webster 1828). Its editor was William Dwight Whitney, a Sanskrit scholar at Yale who had contributed to the 1864 edition of *Webster's New International dictionary* and had written other important language books. The *Century* was intended to cover the language from Middle English onward and included a large number of encyclopedic entries. There were many historical citations. Its coverage of technical terms was especially good, and the OED editors heavily borrowed these (Richard Bailey reported that the OED explicitly cites the *Century* 2118 times and argued convincingly that James Murray was more highly influenced by it than even this figure suggests). Even British reviewers were much impressed by the work, though Murray was originally extremely jealous of the dictionary's success, and made some intemperate remarks in print about it before calming down.

The *Century* was praised, among other things, for its elegant typography, designed by Theodore De Vinne. It was widely used for decades to come, and the book is still not only readable but fresh-looking today. The illustrations were plentiful (about 6000) and beautiful (the dictionary's publisher was also responsible for the admired illustrated *Century magazine*). Definitions were excellent, and the sense divisions were particularly extensive. The noun *matter*, for example, has 17 numbered senses in the *Century,* with three further subdivided, while the 1864 Webster has 10 senses, with none subdivided. Later spinoffs and versions include a supplement of names (1894), an atlas (1897), a partially revised edition in ten volumes (1901), and a greatly reduced two-volume work, the *New Century dictionary of the English language* (1927). The dictionary served as a source for the *American College dictionary,* discussed later in this article, and its citation files were incorporated into and thus served as a basis for the *World Book dictionary.*

Funk and Wagnall

The *Standard dictionary of the English language*, published by Funk and Wagnall in 1893, was a new and

major entrant into the American dictionary market. The publishing firm had been formed only in 1890, and the *Standard dictionary,* containing over 304 000 entries, was assembled in an astonishingly short 3 years, thanks to a huge team of editors and consultants. The book was heavily advertised and was a commercial success. Isaac Kaufman Funk, the editor, explicitly wanted to produce a populist dictionary, and the *Standard* introduced many innovative practices that are still widely followed by practical dictionaries today. Etymologies, previously placed at the start of entries so that a word's history would inform the definitions, were now placed at the end of each entry. Where previous dictionaries had given the definitions in historical order, the *Standard* put the most common meaning of each word first and obsolete or archaic definitions at the end. Modern British dictionaries now use this approach, typically using corpus evidence to determine the comparative frequency of different meanings, but some modern American dictionaries, including *Merriam-Webster* and *Webster's New World*, still use historical order or a slightly modified form of it. Pronunciations in the *Standard* were listed twice: once using a basic key and once using a more precise, though more complicated one. Spelling was a problem: Funk was a member of the Simplified Spelling Board; the emphasis on spelling reform in the Funk and Wagnall dictionaries was not reflected by public acceptance or enthusiasm, and it ended up alienating readers. A second edition, the *New Standard dictionary,* with 450 000 entries, appeared in 1913. Successful at the time, the *New Standard* was never seriously revised, and Funk and Wagnall gradually declined in importance, despite the appearance of a good college dictionary under the imprint in 1963. The dictionary range was broken up, with different Funk and Wagnall copyrights being sold to various mail-order and other marketing organizations, bringing an end to serious lexicographical work on this once great family of dictionaries.

Unabridged and College Dictionaries

After the publication of the so-called Webster–Mahn dictionary of 1864 (discussed in the section "The 'dictionary war' of the mid-19th century"), the next major dictionary from Merriam (who had taken over publishing rights to the Webster dictionaries in the 1840s) was the *Webster's International dictionary* of 1890, which was, like the Webster–Mahn, edited by Noah Porter. This had about 175 000 entries, a large total that was shortly overtaken by the Funk and Wagnall *Standard*. Merriam expanded the *International* in 1900 and in 1909 released *Webster's New International dictionary of the English language,* edited by William Torrey Harris and F. Sturges Allen, which had 350 000 entries. Many of the new terms were technical, reflecting the large number of additions to the vocabulary in the later Industrial Revolution. In 1934, with Funk and Wagnall on the wane, Merriam released the *Webster's New International dictionary of the English language,* second edition (known as Webster's second or W2, though it was in fact the seventh in the line of large Webster dictionaries), edited by William Allan Neilson and Thomas A. Knott. Webster's second remains the largest English dictionary ever published (based on entry count), with over 600 000 entries. It was strong in both new words and archaic or rare ones, which were relegated to a separate section running along the bottom of the page.

The publication of *Webster's third New International dictionary, unabridged* (Webster's third, or W3) in 1961, brought about a remarkably intense and public debate about the nature and purpose of dictionaries. Its editor, Philip B. Gove, had made some idiosyncratic editorial decisions that, combined with an intense and somewhat misleading marketing campaign on Merriam's part, brought broad condemnation upon the dictionary from many critics.

Though much of W3 was not in fact tremendously innovative, it had a number of noteworthy features. The pronunciation system was very detailed but rather difficult for many people to understand; in particular, variations were listed by using symbols to indicate words or parts of words that were previously described. Encyclopedic entries were dropped entirely, and a cutoff date of 1755 (the date of Johnson's dictionary) was adopted for obsolete words. There were many fewer illustrations than in W2. The definitions were written in an idiosyncratic style, with the entire definition presented as a single "completely analytical one-phrase definition" (Preface, page 6a) with commas used only to separate words in a series. The key information was given first, followed by logical groupings of related information. This resulted in some unwieldy entries, particularly for nouns, where a definition sometimes ran on to great length, with no distinction between essential and supplementary explanatory information. Much of the information presented in W3 was in fact taken from W2, where, however, it was presented more readably in a number of separate sentences. An example condemned by critics was the entry for *door.* The main definition in W2 was "The movable frame or barrier of boards, or other material, usually turning on hinges or pivots or sliding, by which an entranceway into a house or apartment is closed and opened." W3 expanded this definition to:

> A movable piece of firm material or a structure supported usu. along one side and swinging on pivots or hinges, sliding along a groove, rolling up and down, revolving as one of four leaves, or folding like an accordion by means of which an opening may be closed or kept open for passage into or out of a building, room, or other covered enclosure or a car, airplane, elevator, or other vehicle.

Similarly, the definition for *flame* extended for 20 lines, and that for *hotel* continued for 11 lines.

The most extensive debate, however, concerned W3's treatment of usage issues. Philip Gove made a number of decisions that came to be harshly criticized. Register labels were few; the 'informal' and 'colloquial' labels were dropped entirely, and 'slang' and 'nonstandard' were notably uncommon. There were very few usage notes or other forms of explicit usage guidance. The dictionary examined uses of poorly educated users of English, not just writers of high-style literature. All of these were supportable on scholarly grounds, but were felt by the critics to be an abdication of the dictionary's purposes of being a 'supreme authority' on the language, as earlier Merriam publicity material had bragged. Harsh reviews appeared in many prominent periodicals and by notable authors, including Jacques Barzun in the *American Scholar,* Dwight Macdonald in *The New Yorker,* and Wilson Follett in *The Atlantic Monthly.* Many of their objections were erroneous, some were misleading, and most were based on a fundamental disagreement about the purpose of a scholarly dictionary. Typical was the reaction to the entry for *ain't*. The first sense, covering the meanings 'are not/is not/am not,' carried no usage label, although it did have a note reading "though disapproved by many and more common in less educated speech, used orally in most parts of the U.S. by many cultivated speakers." The second sense, 'have not/has not,' was labeled 'substandard.' Although this assessment accurately reported the findings of scholarly studies of American speech, it was widely held to be insufficiently damning of the use of the word.

The first so-called 'college' or 'collegiate' dictionary (this last word is a trademark of Merriam-Webster) was Merriam Webster's *Collegiate dictionary* of 1898. This was in effect nothing more than a medium-sized general-purpose dictionary, explicitly abridged from larger Merriam works.

It was Clarence Barnhart's *American College dictionary* (ACD) of 1947 that established this kind of dictionary as a distinctive genre. Based broadly on the *Century dictionary*, the ACD was compiled with the aid of specialists in many fields and included explanations of many technical and scientific terms of a kind that could be expected to be useful to college students. It also reflected (or purported to reflect) work in American linguistics: ACD's Editorial Advisory Committee included Leonard Bloomfield, Charles C. Fries, W. Cabell Greet, Irving Lorge, Kemp Malone, and other prominent linguists of the day. It was the first dictionary to include a schwa in pronunciations, but otherwise the pronunciations used a 'spelling–rewrite' system, with accented vowels, rather than the International Phonetic Alphabet (IPA). Instead of the historical ordering of senses, the ACD arranged its definitions with the most common current meaning in first position, so that early but obsolete senses were shuffled to the bottom (as we have seen, this practice was pioneered in the Funk and Wagnall *Standard dictionary* but had not spread to college dictionaries).

The ACD also incorporated all entries, including foreign terms and biographical and geographical listings, into a single alphabetical word list. The ACD was the basis of later Random House dictionaries, and in turn spawned the 1971 *Hamlyn encyclopedic World dictionary* in England, which was itself used as the basis for the *Macquarie dictionary* family in Australia.

Webster's New World dictionary, college edition (WNWD) was first published in 1953 under the editorship of David Guralnik and Joseph H. Friend. A second edition, edited by Guralnik, appeared in 1970. As in the Merriam dictionaries, the senses in WNWD were historically ordered, but unlike Merriam and like ACD, it included all terms in a single alphabetical list. In other words, names of famous people and places, abbreviations, foreign phrases, etc., were included in the main word list, rather than being relegated to supplements. The definitions of WNWD, especially its technical terms, were notably clear and easy for the nonspecialist to read; its etymologies, too, were full and clear. This practice has been maintained in later editions, edited by Victoria Neufeldt (1988) and Michael Agnes (1999). WNWD has long been the dictionary of choice of some leading news organizations, e.g., the *New York Times* and the Associated Press.

The Post-*Webster's Third* Dictionaries

The reaction to Webster's third led directly to the publication of two major dictionaries. Random House decided to produce an expanded version of the *American College dictionary.* Edited by Jess Stein Laurence Urdang, the *Random House dictionary of the English language, unabridged* (RHD) appeared in 1966. It retained most of the lexicographic practices of the ACD, including organization of senses with the modern meaning first and a unified alphabetical list incorporating biographical and

geographical names. The RHD also added encyclopedic features, such as a color atlas and short bilingual dictionaries of French, Spanish, German, and Italian. However, it is not truly an unabridged dictionary but rather a bulked-up college dictionary. Definitions were considerably easier to read than those of Webster's third but were still relatively thorough. The coverage of technical vocabulary and slang was particularly good. In 1968 a cut-down version of this work appeared as the *Random House College dictionary,* taking the place in the market of the ACD. This, too, was noted for its excellent attention to technical vocabulary and slang. A second edition of the RHD appeared in 1987, edited by Stuart Berg Flexner, adding some 50 000 entries. It also added more substantial encyclopedic entries, including names of important literary works, and the etymologies were heavily reworked and quite thorough. Like the more recent Merriam dictionaries, RHD2 etymologies indicated the earliest known date of a word's use, although unlike Merriam it printed this as a range of dates, such as '1950–55' or '1830–40,' to suggest the impossibility in most cases of knowing the exact coinage date.

Also as a direct result of the W3 furor, the American Heritage publishing company tried to buy Merriam outright. Its president called Merriam "atrociously managed," thought that "Merriam's great scholarly reputation ha[d] become tarnished in recent months through the publication of the radically different Third edition," and announced his intention to put the third edition out of print while working on a new edition. When these efforts failed, American Heritage began work to produce a new dictionary to compete with W3. Originally planned as an unabridged dictionary, when the *American Heritage dictionary* (AHD) finally appeared in 1969 it turned out to be closer in scope to a typical college dictionary than to an unabridged dictionary. Physically, though, it was much larger than other college dictionaries, not because it contained more text but to make room for many photographic illustrations, which appeared in a side column in the margins of each page. This feature was always a hallmark of this dictionary line, while other dictionaries had used line drawings incorporated into the text. Color photographs first appeared in the fourth edition of AHD.

One of AHD's most notable features was the establishment of a 'usage panel,' whose members' comments on various disputed or debatable aspects of American English usage were reported at the dictionary's entries for the relevant words. The panel was composed chiefly of older, conservative male writers, some of whom had been deliberately chosen for their hostility to W3. Though linguists criticized the panel on many grounds, it was a major publicity boon for the dictionary. In more recent editions of the dictionary, the Usage Panel has been chaired by Stanford linguist Geoffrey Nunberg, who moved AHD's many usage notes away from the yes/no style of earlier editions to a more balanced, descriptive discussion of usage problems, with the usage panel – itself more balanced – adding an extra dash of opinion, rather than forming the entire basis of entries. For example, the usage note for *hopefully* in AHD1 read, in its entirety:

> *Hopefully,* as used to mean "it is to be hoped" or "let us hope," is still not accepted by a substantial number of authorities on grammar and usage. The following example of *hopefully* in this sense is acceptable to only 44 percent of the Usage Panel: *Hopefully, we shall complete our work in June.*

The usage note for this word in AHD3 (1992) goes on for a half-column, discussing syntactic parallels, potential ambiguity, the changing acceptance of the usage by the Usage Panel (it was significantly less acceptable in 1992 than it had been in 1969), and the issues facing the writer who chooses to use it.

Another distinguishing characteristic of the AHD was its extensive appendix of Indo–European roots contributed by the Harvard linguist Calvert Watkins. The appendix was highly appreciated by a small community of scholars and serious word buffs and helped establish AHD as a serious dictionary. It was also very long and not considered helpful for the more typical reader. It was therefore removed from the second edition and published separately, but was reinserted into later editions.

Although the AHD was established for linguistically conservative motives, it was, ironically, the first general American dictionary to include an entry for the word *fuck*. Its definitions and sense divisions were on a par with other contemporary dictionaries. As in other American dictionaries, comparatively little attention was paid to lexical syntagmatics and collocations, so that, for example, the verb *put* is labeled *v.t.* (verb transitive), with no mention of the obligatory adverbial argument (e.g., *put it down, put it on the table*).

The AHD was also the first dictionary to make any use of an electronic corpus, with the 1-million-word Brown Corpus assembled in the 1960s. However, this did not have a serious impact on the dictionary, as a 1-million-word corpus is simply too small to enable a lexicographer to distinguish significant co-occurrences of words from chance cooccurrences (*see* **Corpus Lexicography**). Still, the dictionary's interest in and support for corpus-based lexicography was manifested in principle by devoting three pages

of the front matter to an article on 'Computers in language analysis and in lexicography' by Henry Kučera. The company later published the *American Heritage word frequency book* (1971), based on a 5-million-word corpus of school texts, and used it in thepreparation of the *American Heritage School dictionary.*

The 1990s: The Emphasis on New Words

The first important American dictionary of the 1990s was *Random House Webster's College dictionary* (RHWCD; 1991), a successor to the *Random House College dictionary* of 1968 but based on RHD2. The RHWCD was attacked on various grounds following publication. Merriam-Webster sued Random House for trademark infringement. In the 19th and early 20th centuries the Merriam-Webster company had neglected to register the name *Webster* as a trademark. In the early 1950s they had sued the publishers of *Webster's New World dictionary* for using the name *Webster* and lost. The use of the name *Webster's* was judged to be generic for dictionaries. Now, however, Merriam-Webster argued that the use of *Webster's* in a similar typeface on a red cover was confusing to customers of their *Collegiate dictionary.* Although a court found in favor of Merriam, a federal appeals court then reversed this ruling. Random House had, in the meantime, altered the cover design of the RHWCD to be less similar to that of Merriam-Webster's.

With regard to its content, the RHWCD was published at a time when interest in so-called political correctness was high. It was the first dictionary to include a definition for the term *politically correct* itself, defining it as "marked by or adhering to a typically progressive orthodoxy on issues involving esp. race, gender, sexual affinity, or ecology." It was the first dictionary to include entries for such terms as *womyn, herstory, waitron,* and *chairpersonship,* and it also had an essay titled "Avoiding sexist language" (later expanded and retitled to "Avoiding insensitive and offensive language"). The dictionary was attacked in the press for these steps, although the entries were based on real evidence and the usage advice given was sound, straightforward, and uncontroversial.

For a few years, the RWHCD took advantage of its computerized editing system to produce frequent heavy updates. In the past, new editions of college-sized dictionaries had appeared at roughly 10-year intervals, with changes in the intervening period being limited to very small corrections. The RHWCD produced new versions almost annually, with each containing several hundred new entries. The marketing bonanza that this provided – a guarantee of heavy press coverage at each new release – proved too tempting to resist, and soon most other college dictionaries began to do the same.

American Dialect Lexicography

The American Dialect Society (ADS) was founded in 1889 with the intention of creating a comprehensive dictionary of American dialects that would serve as a counterpart to Joseph Wright's *English dialect dictionary.* The publication series *Dialect notes* was started in 1890 as a basis for this effort. The glossaries published therein were minimalist, but it was never the intention for them to be built up into an actual dictionary – rather to get people started on the work of data collection. *Dialect notes* continued to be published for several decades, but eventually World War I and then the Great Depression drained away both the energy and the funding for the completion of the larger project.

Eventually, Harold Wentworth, with the encouragement of the ADS's Louise Pound, decided to publish his own dialect dictionary, the *American dialect dictionary* (ADD), which appeared in 1944. The ADD was less than satisfactory – a single, medium-sized volume that included only 15 000 terms. It heavily mined *Dialect notes* and added some poorly referenced quotations from other sources. The illustrative quotations are almost uselessly short. There are no general regional or social labels and no etymologies.

For some time, Frederic G. Cassidy had been pushing the ADS to resume serious work on its dictionary. Trained at the University of Michigan, Cassidy had been an editor on the *Early Modern English dictionary* (publication of which was eventually abandoned), the *Middle English dictionary,* and the *Linguistic atlas of the Great Lakes.* Eventually, with his enthusiasm showing no signs of waning, the ADS appointed Cassidy the editor of its dictionary, the *Dictionary of American Regional English* (DARE).

The DARE was a scholarly work devoted to the collection, mapping, and explication of American regionalisms. Four volumes, covering the range from A to the middle of S, had been published by 2004. The DARE was based primarily on fieldwork undertaken between 1965 and 1970. Fieldworkers interviewed informants in more than 1000 communities, with an extensive questionnaire including nearly 2000 questions covering all aspects of daily life. Cassidy modeled the questionnaire on one for the *Wisconsin English language survey,* which he had designed in the 1940s, incorporating many improvements after seeing how people responded to it.

The survey results were supplemented with many additional quotations from other sources, including other historical dictionaries, the records of the *Linguistic atlas of America*, a dedicated reading program, and a variety of published and unpublished research in American dialectology. The DARE also has extensive coverage of certain areas neglected in other dictionaries, for example, natural history terms (variations of plant and animal names are astonishingly fully covered) and children's games. Details of regional pronunciations are given, based on tape recordings or close phonetic transcriptions made of many of the interviews.

The DARE results were presented in the familiar form of a historical dictionary, with the notable addition of maps to illustrate certain entries. These maps showed the location of individual responses and were distorted to show the population density of each state, rather than its area. The DARE was also notable for basing its geographical and social labels on a statistical analysis of the actual survey data, rather on subjective impressions. The project made extensive use of computers to process this data and generate the maps, at a time when humanities computing was in its infancy. Frederic Cassidy died in 2000, after the publication of three volumes of DARE; Joan Hall, who had been Associate Editor under Cassidy, took over as Chief Editor.

Dictionaries of Americanisms

The fact that American English and British English had differences was apparent as early as the 17th century, when travelers – British ones – began to observe that American English speakers had words not in use in Britain and that some existing words were used with different meanings. The stigmatization of American English is attested from 1735, when a British traveler to Georgia referred to *bluff,* an Americanism for 'a cliff,' as 'barbarous.'

Though the first suggestion of a separate dictionary or glossary of American English is found in 1754, when a Londoner anticipating the 1755 publication of Johnson's *Dictionary* proposed that it should have a supplement devoted to Americanisms, it took quite a bit more time for this suggestion to be realized. The first separately published dictionary of Americanisms was John Pickering's 1816 *A vocabulary, or collection of words and phrases which have been supposed to be peculiar to the United States of America.* (It had been published a year earlier as part of the collections of the American Academy of Arts and Sciences.) Pickering, who came of a prosperous and well-established New England family, was highly educated. He worked as a lawyer, but had turned down the professorship of Hebrew and Oriental Languages at Harvard, and later Harvard's professorship of Greek; he published works on several Native American languages and an important Greek–English lexicon for school use. Pickering's attitude toward American English was hostile; he strongly supported the authority of England, and his motive in collecting American words was to show Americans what words should be avoided. The *Vocabulary* contained only about 500 words, comprising genuinely new forms, new senses, and American survivals of obsolete British words. The work was well received by much of educated America but intensely disliked by the linguistically patriotic Noah Webster.

In 1848, John Russell Bartlett – better known for his dictionary of quotations – published his *Dictionary of Americanisms.* Though Bartlett had gotten started on this work by making marginal comments in a copy of Pickering, he soon realized that his notes were more extensive than the original. Unlike Pickering, Bartlett gloried in the American tongue, becoming particularly entranced by the frontier narratives of or attributed to Davy Crockett. His dictionary was filled with words regarded as provincial or vulgar, and was illustrated with citations from appropriate sources, such as backwoods tales or letters from rural folk. The book became very popular, going through four editions through 1877, each with significant revisions and additions; in particular, its coverage of slang increased notably.

Other dictionaries of Americanisms include Alfred L. Elwyn's 1859 *Glossary of supposed Americanisms,* a short work devoted to archaic Briticisms surviving in the United States; Maximilian Schele de Vere's 1872 *Americanisms,* a somewhat discursive book organized by the source language, giving emphasis to borrowings from French, Dutch, Spanish, and Native American languages; John S. Farmer's 1889 *Americanisms old and new,* by an Englishman, which contained citations and relatively full definitions for many American terms; and Richard H. Thornton's *American glossary,* an extensive book (two volumes as published, with substantial additional material appearing in a later volume of *Dialect notes*) based on a vast amount of citation evidence.

There are two great scholarly dictionaries of American English, both of which focus on vocabulary differences between Great Britain and the United States. The *Dictionary of American English* (DAE) was begun in 1925 under the editorship of William Craigie, one of the editors of the OED. In 1919 Craigie had proposed a range of dictionaries based on historical principles devoted to different regional and temporal varieties of English, giving more detail than OED could. The DAE was the first of these.

(Craigie was also the founding editor of the *Dictionary of the older Scottish tongue*; *see* **Scots Lexicography**.) He was appointed a professor of English at the University of Chicago to start work on the DAE, and kept his OED role at the same time. An extensive reading program was established under the direction of George Watson, who had followed Craigie from the OED. The DAE appeared in four volumes from 1938 to 1944 and included words and senses that arose or were particularly common in the United States, as well as those with some special connection to American life. A cutoff date of 1900 for citations was adopted as the latest date for inclusion.

In 1951 Mitford M. Mathews, one of Craigie's assistants on the DAE, published the two-volume *Dictionary of Americanisms* (DA). This dictionary was limited to words and senses that had originated in America (in contrast to words used there), giving more detail of such terms than DAE, and paid special attention to foreign borrowings. The DA had no date cutoff, and its coverage of early 20th-century English is thus especially important, not duplicating OED or DAE material, and especially good on slang. Since DA was focused so strongly on origins, it occasionally led to somewhat unexpected absences: terms used exclusively in America were excluded if they had been originally British even if they had become obsolete in Great Britain.

Current and Future Trends in American Lexicography

It must be acknowledged that American lexicography is currently in a state of comparative stagnation. As we have seen, for 140 years, from 1830 (Webster and Worcester) to 1969 (American Heritage), competition in the marketplace encouraged imaginative innovations in American lexicography, but from 1970 on these same market forces discouraged innovation. Leading dictionary publishers, having achieved market supremacy, concentrated on keeping prices down rather than on creating expensive (and commercially risky) new departures or responding to advances in linguistic theory and exploiting new potentials. The publishers have been unconsciously abetted by the focus on syntactic abstractions and consequent neglect of actual usage and cultural norms that was characteristic of mainstream American linguistic theory from the 1960s to the 1990s. The result has been a difficult commercial situation for everyone, with publishers being unwilling to risk the significant investment required for new work to produce dictionaries that might turn out to be of potentially limited popular acceptance, while investing heavily in maintaining the status quo was hardly more attractive. In 2001, the publisher Random House disbanded its entire reference department, putting a sad end to an important strand in the American lexicographical tradition and following Funk and Wagnall into oblivion.

Most current American English dictionaries still make little use of corpora, preferring introspection, sporadic citation collection, or unsystematic use of databases as ways of obtaining evidence. The focus on explaining meanings, rather than showing how words are used, is very striking when comparing American dictionaries with dictionaries of European languages such as German or Greek, where more space is devoted to illustrating words in use than to explaining their meaning. An exception is the *New Oxford American dictionary* (NOAD; 2001), an Americanization of a British dictionary, the *New Oxford dictionary of English* (NODE, 1998; *see* **English Lexicography**), which cites corpus evidence extensively as well as using traditional sources such as citations from literature and scientific textbooks, and which offers a more delicate account of word grammar than is usual in American dictionaries. The NOAD copied the style of NODE but adapted certain features to make it more suitable for an American audience. For example, in pronunciations, the IPA of the British dictionary was replaced by a respelling system with diacritics. Some of the more complicated grammatical explanations were simplified or omitted; the word *determiner* was dropped as a part-of-speech label. Illustrations (line drawings and photographs) were added and the number of encyclopedic entries was increased. In all, NOAD, though based on a British work, represents an interesting departure in American lexicography. It remains to be seen whether other U.S. dictionary publishers will respond in any significant way.

Academic research projects such as WordNet (*see* **WordNet(s)**) and FrameNet (*see* **Frame Semantics**) point the way forward, in the sense that they exemplify the potential of computer technology for lexicography, but neither is a dictionary. WordNet is a collection of synonym sets that are linked together to show semantic relations among concepts. It has wide coverage, but the lexicography leaves much to be desired, and it owes nothing to empirical analysis of the actual use of words. FrameNet relates word usage and potential word usage to a number of semantic 'frames.' It proceeds frame by frame rather than word by word; thus, it only describes word uses that are relevant to particular semantic frames. It does not attempt systematically to discover how many different senses a word has, and indeed the concept 'word sense' does not play much of a part in FrameNet's theoretical apparatus. Perhaps its greatest importance

is that it shows how corpus evidence can be linked to linguistic theory. The field is wide open for a new initiative, inspired by such developments, that will take advantage of computer technology, corpus linguistics, and cognitive linguistics to create an empirically well-founded, corpus-based study of current American English usage, showing how each word in the language is used and how the meanings are related to usage.

Amharic

D Appleyard, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introductory Remarks

Amharic (self-name *amariṇṇa*) is the largest member of the South Ethiopic branch of Ethiopian Semitic languages. Amharic is spoken, according to the most recent estimate (1999), by around 17.4 million people as a first language and between 5 and 7 million more as a second language, making it the second largest Semitic language after Arabic, and the fourth largest language of sub-Saharan Africa after Swahili, Hausa, and Yoruba, although some estimates suggest that Oromo may have more speakers in total. Amharic is the main lingua franca of Ethiopia and is the constitutionally recognized working language of the country. As such it forms the language of instruction of public education at primary and secondary level, including from the third grade upwards in areas where it is not the first language. It is also the majority language of most urban-dwelling Ethiopians except where Tigrinya (Tigrigna) is the first language. The current status and wide distribution of Amharic are due especially to the amharization policies of previous Ethiopian governments in the 20th century. Until the change in language policy after the Ethiopian revolution of 1974, Amharic was the only Ethiopian language used in state education and the official media. The earliest records of Amharic date to the rise of the Amhara or Solomonid dynasty in the 14th century, and the spread of the language over an ever-increasing area of the Ethiopian highlands accompanied the expansion of the Christian kingdom up to modern times.

Modern Amharic shows some dialectal variation, though perhaps less than might be supposed for a language with such a wide distribution. This may in fact be due to the way in which the language has spread over the last 700 years, as part of a deliberate process of amharization, and it is notable to this extent that the dialect areas that are generally

American Linguistics before Whitney

M Amsler, University of Wisconsin–Milwaukee, Milwaukee, WI, USA

Language study in North America from the early colonies to 1860 was founded on three discourses: 'Americanisms' – the divergence of U.S. from British English; 'Federal English' – the politics of English as a nation language; and 'Indian languages' – questions of language typology, evolution, and genetic classifications. By the mid-19th century language study was becoming increasingly professionalized, and the discourse on Indian languages and linguistic typology helped place U.S. language study on a global footing with 'scientific' German scholarship.

Colonial Period to 1812

The principal European backgrounds for North American language studies were British rhetoric and prescriptivism (Beattie, Lowth), French Ideologues' rationalist thought (Destutt de Tracy, Volney), compendia of vocabularies (e.g., Pallas's *Linguarum totius orbis vocabularia comparativa*, 1787–1789), and later, German philology (Grimm, Rask, Bopp).

In England, Robert Lowth (*A short introduction to English grammar*, 1762) railed against vulgarisms perpetrated by uneducated speakers and writers and against the wrongheaded usage at court and on the stage. Lowth and V. J. Peyton claimed that English grammar should be governed by the received categories of Latin grammar, and they proscribed such forms as multiple negation and *which* for animate references. Samuel Johnson hoped to purge English's idiosyncratic usages (*A dictionary of the English language*, 1755), symptoms of "the boundless chaos of a living speech" (Preface, 4th ed., 1774).

French linguistic relativism and a rationalist, secular approach to grammar and usage, as presented in Volney's *Ruines* (1791) and Destutt de Tracy's *Idéologie* (1803–1818), were favorably received among colonial intellectuals such as Franklin and Jefferson. Volney based his project to understand "reason equally distributed in each human being" on a taxonomy of "the history of peoples on the basis of the history of their language" (1819). Jefferson owned works by Destutt de Tracy and Volney; the British etymologist and parliamentary reformer Horne Tooke's influential *ΕΠΕΑ ΠΤΕΡΟΕΝΤΑ or, The diversions of Purley* (1789–1805) (*see* **Tooke, John Horne (1736–1812)**); Old English grammars; and studies of Bengali, Persian, and other non-European languages. Franklin loaned Webster his copy of Tooke's *Diversions*. Early U.S. language study enfolded the egalitarian principle of universal reason and ethnology's evolutionary study of human society through language history within a revolutionary democratic nationalism.

Prescriptivism

In pre-Revolution America, few English grammars were available for vernacular education, despite the popularity of Lowth and other prescriptivists. The *New England primer* (1680–1690) and Thomas Dilworth's *A new guide to the English tongue* (1747) were primarily spellers with little grammatical material. These early textbooks adopted the traditional definition of grammar as "the art of speaking and writing correctly" but provided little in the way of actual grammatical analysis or terminology.

When the American Revolution ended in 1783, grammar and grammar education were divided between prescriptive and national language ideologies. The most influential continuer of the prescriptive tradition was Lindley Murray, a Quaker and Tory supporter who fled to England after the Revolution. Murray modeled his *An English grammar, adapted to the different classes of learners* (1795) on Lowth's grammar and argued that ideal usage in the new United States should be a middle commonsense style, avoiding both affected court usage and lower class barbarisms. Noah Webster's (1758–1843) career reflected the shift from modified prescriptivism to 'Federal English' in the United States (*see* **Webster, Noah (1758–1843)**). Webster distinguished between acceptable educated and uneducated usage and noted that U.S. English's divergence from British English was politically inevitable and necessary. Generally, he subordinated prescriptive grammar to usage: "It is our business to find what the English language *is*, and not, how it *might have been made*" (*A grammatical institute of the English language*, part 1, 1783).

Divergence

Long before Webster, colonial observers had noted differences between British and American English usage. Many eagerly described the distinctiveness, creativity, and innovation rather than the vulgarity of English usage in North America. In a series of articles in *The Pennsylvania journal* (1781), Rev. John Witherspoon (1722–1794), Scots clergyman and president of the College of New Jersey (later Princeton University), claimed to have coined the term *Americanisms* ("ways of speaking peculiar to this country") analogous to the term *Scotticisms*.

Witherspoon organized his list of vocabulary and usages according to vulgarisms, local terms, common blunders, ignorance, cant phrases, personal blunders, and new technical terms. However, Witherspoon criticized specific usages on both sides of the Atlantic and thought many Americanisms diminished the English language. Relying on the authority of the 'best' English writers, he proscribed local phrases from people of all ranks, including such Americanisms as *bison, once in a while, raw salad, chunks, occasion* ('opportunity'), *tot(e)* ('carry,' identified as a Southern regionalism), and *bluff*. *Bluff*, meaning either a 'steep river bank' or 'misleading someone with a false front,' became a stock marker of American speech in 19th-century literature (Cooper, Lewis and Clark, Tennyson). Witherspoon also proscribed the spread of cant phrases or slang among mainstream speakers, including distinctive American expressions such as *taken in, bilked, the thing* ('quite the thing'), *bamboozle, mob, vastly* (adv. from *vast*), *topsy turvy,* and *upside down*.

Nonetheless, Witherspoon also situated U.S. English within a distinctly American national project for intellectual independence. He recommended "a pure and, as it may be called, classic simplicity," enhanced by linguistic independence and nation building: "Time and accident must determine… whether we will continue to consider the language of Great-Britain as the pattern upon which we are to form ours: or whether, in this new empire, some center of learning and politeness will not be found, which shall obtain influence and prescribe the rules of speech and writing to every other part" (1802).

Witherspoon's wordlists sparked others. David Humphrey's (1752–1818) very popular glossary of Americanisms ("new-coined American, obsolete English, and low words in general") was appended to his published play *The Yankey in England* (1815). Humphrey's glossary was used by later writers on Americanisms, including John Pickering (*Vocabulary*, 1816) and John Russell Bartlett (*Dictionary of Americanisms,* 1848). Humphrey noted three levels of usage based on education: college, middle-class grammar school, and limited schooling in free public schools. He paid special attention to loan words and non-English languages in America: German, Dutch, Spanish, French, and Indian languages. Humphrey's citations sometimes reflect regional pronunciations, not new Americanisms *per se* – *ax* (ask), *berrying* (burying), *cuss* (curse) – and he is critical of low-class vulgar speech. Moreover, his explanations are not always reliable. He incorrectly interprets *Ant I* as probably from *and I*, when in context the phrase is clearly the tag question *ain't I*.

The recognition of differences between U.S. and British English and the politics of establishing a national Federal English constrained rationalist language reforms. Webster's spelling reforms (*iland* instead of *island*) based on pronunciation were only partly accepted. John Adams (1735–1826) proposed a U.S. language academy "for refining, correcting, improving, and ascertaining the English language" (letter to Congress, Sept 5, 1780), but the plan was never accepted. As a rationalist reformer, Adams believed a national language academy would produce "a public standard for all persons in every part of the continent to appeal to, both for the signification and pronunciation of the language." However, Jefferson, Webster, and others associated language change and variation with freedom and democratic ideals and strongly opposed the establishment of an official body to regulate language usage in the United States (Heath, 1977).

American Indian Languages

Triggered by language contact, many European colonists showed great interest in North American Indian languages, not only for cross-linguistic communication and survival in the New World but also because of the humanist belief in language as constitutive of reason, civilization, and social order. Before sailing for North America, Thomas Harriot learned 'Algonkian' (East Carolina Cherokee) from two Indians in England, who in turn learned English from Harriot (*A briefe and true report of the new found land of Virginia,* 1588). His wordlist included observations about grammatical structure (e.g., genders of number words) and syntactic rules. Roger Williams (*A Key into the language of America*, 1642) and John Eliot (*The Indian grammar begun*, 1666; *The Holy Bible: containing the Old Testament and the new translated into the Indian language*, 1663) described Narraganset and Massachuset vocabulary, idioms, and pragmatics as keys to the tribes' cultures, myths, narrative traditions, and customs. Williams posited rules for Narraganset plurals and sentence formation and praised Narraganset's "copiousness" (multiple words for one thing), although he claimed the language lacked abstract nouns. He also suggested that Indians' religious practices had affinities with the ancient Hebrews', although their languages more resembled Greek. Other colonial writers included Indian vocabulary lists with their ethnographic and geographic accounts of the New World. Loan words from Indian languages were limited, but some were given high profile in early American literature, especially placenames and words from Algonkian (Algonquian) languages (*moccasin, papoose, squaw, toboggan, tomahawk, moose,*

opposum, pecan, squash, skunk, terrapin, woodchuck).

Many European scholars described the American colonies as the New Eden and thought the continent's original non-European inhabitants might provide a link to the lost universal language spoken before Babel. In an evolutionary model, linguists and compilers such as Wilhelm von Humboldt had claimed that Indian languages were less complex than European ones and therefore historically more 'primitive.' But more informed colonial observers, such as the Plymouth colony's Edward Winslow, recognized that Indian languages were "copious, large, and difficult" (*Good newes from New England,* 1624). Williams realized that the language the Indians taught to the colonists was often not their "complex" native language but a pidgin variety. Indians in turn acquired pidgin Englishes in their interactions with the colonists and sometimes used pidgin English in their exchanges with other tribes (Christopher Levett, *A voyage unto New England*, 1624; Jonas Michaëlius, 'Letter,' 1628).

Early colonists were puzzled as to how to transcribe Indian languages. Many Indian language phonemes were unfamiliar to them, and travelers noted that Indian languages were difficult for Europeans to pronounce. Observers recorded Indian speech with whatever phonetic spelling they could produce. Williams was the first to recognize the phonological variation among *n, l,* and *r* in several Algonkian languages, and he used special diacritical marks to indicate pronunciation features of Narraganset (Williams, 1642/1973). But his analysis did not extend to the entire Narraganset sound inventory. Searching for a more scientific representation of linguistic sounds, Harriot invented 'An universall Alphabet conteyninge six & thirty letters,' one character for each sound. He transcribed 'Algonkian' (Cherokee) language in the Carolinas so that any reader could pronounce the words properly (*Briefe and true report*). Harriot's transcription/notation system did not become well known – Williams was unaware of it – but his work may have influenced Samuel Hartlib's phonetic notation system (1635).

Federal English and Language Study, 1783–1830

After the American Revolution, the U.S. struggles over national identity were played out in language politics and linguistic discourse as well as in political, cultural, and military arenas. The independence of American English was an important topic in public discourse as well as in linguistic writing, dictionary publishing, and school texts. In addition, new ethnographic research on Indian languages and genetic relationships based on language typology set the stage for a U.S.-inflected comparative linguistics. By 1830 American philologists and ethnographers were energetically undertaking worldwide comparative linguistic and ethnographic research and elaborating theoretical and analytic vocabularies for comparative-historical linguistics.

Noah Webster celebrated the variety in American usage while also promoting a strong American language tradition for national stability: "Custom, habits, and *language*, as well as government should be national." Linking language and revolution, Webster rejected British authority in English usage: "As a nation, we have a very great interest in opposing the introduction of any plan of uniformity with the British language, even were the plan proposed perfectly unexceptionable." Webster's ideal U.S. speakers were the "American yeomanry . . . masters of their own persons and lords of their own soil. These men have considerable education." With myopic idealism, Webster reiterated colonial accounts of American speech as a linguistic Eden: "The people of America, in particular the English descendants, speak the most *pure English* now known in the world. There is hardly a foreign idiom in their language" (*Dissertations,* 1789).

Many of Webster's proposed spelling reforms were distinctly phonetic and sometimes at odds with accepted mainstream literate usage: use single consonants where British spelling uses double consonants (*traveled,* not *travelled*), eliminate silent letters (*crum, iland*) or silent final vowels (*determin, ax* for *axe*), and respell borrowed words as English morphemes (*controller*, not *comptroller*). He approved the U.S. pronunciation of *lieutenant* ([lutənənt]) and recommended *aluminum* instead of the British *aluminium* (*American Dictionary*, 1828). Webster recognized that historically and geographically languages and dialects drift, so that "in a course of time, a language in North America, [will be] as different from the future language of England, as the modern Dutch, Danish, and Swedish are from the German, or from one another" (*Dissertations,* 1789). Departing from prescriptivism, Webster privileged speech over writing. He argued that the alphabet should serve orality and that phonetic spelling reforms would reduce regional and class differences among English speakers, enabling the "plain unlettered man" to have more access to written texts: "It is important that the same *written words* and the same *oral sounds* to express the same ideas, should be used by the whole nation" (*American dictionary*, 1828).

Conceptually, Webster's *Compendious dictionary of the English language* (1806) and later his *American Dictionary* (1828) furthered his Federal English

project by including as many distinctive Americanisms (e.g., *appreciation, subsidize*) as possible while historically linking current U.S. English usage to Anglo-Saxon roots. Webster's etymological strategies justified current usage or sometimes reconstructed the originary proper word that should supersede contemporary usage. Some of Webster's derivations and etymologies, especially those modeled on Tooke's, were criticized by Pickering, and in post-1860 editions of his *American dictionary* many etymologies were purged by a German-trained linguist (Andresen, 1990). But Webster's commentary on the different pronunciations of *ask* (*ask, aks*) reflects a more nuanced mix of pronunciation, spelling, and usage: "The latter is the true pronunciation of the original word; the Saxon verb being written *acsian* or *axian*. The transposition of letters which gives the present orthography and pronunciation is a modern innovation by writers; but it has not changed the primitive pronunciation among the body of our people, and it is doubtful whether a complete change can ever be effected" (*Compendious dictionary,* 1806). For Webster, modern, polite speech is a literate intervention irrationally creating greater distance between pronunciation and spelling, while the Saxon etymon supports a more 'original' (pure) pronunciation, even though it had become stigmatized as nonstandard, 'provincial' speech (e.g., Adiel Sherwood, in *Gazetteer of the state of Georgia*, 1837).

John Pickering's *Vocabulary of words and phrases which have been supposed to be peculiar to the United States of America* (1816) challenged Webster's account of English origins and distinguished true Americanisms from those of "doubtful authority," based partly on Pickering's observations of British usage in London. Pickering referred to his text as not a dictionary but a "glossary of provincialisms," not all of which would be legitimate for a real dictionary. With modified prescriptivism and intellectual nationalism, Pickering aimed to preserve "the English language in its purity" throughout the United States as a service to the "literature and science" of the nation. He adopted the written standard of 'classic' British writers (Milton, Pope, Swift, Addison) for written English in the United States and recommended that if the new nation was to attain international legitimacy, American writers must use a written English that "Englishmen can read with pleasure." However, Pickering also accepted regional spoken English as part of American identity, different from the current British standard. Pickering's views on etymology and written standard English infuriated Webster. Pickering also criticized grammatical improprieties and 'vulgar' usage (*a[i]n't, see* for *saw*) while noting distinctive U.S. forms or phrases (*mighty* for *very*, *attain* without *to*, *averse to* rather than *from*).

By 1830, Witherspoon, Adams, Webster, and Pickering's modified linguistic prescriptivism was no longer the dominant discourse. Even Pickering, in his article 'Americanisms' (*Encyclopedia Americana*, 1830), wrote, "Authority, in regard to language, will go far, but never can withstand for a long time the energies and wants of a free, industrious and thinking people." More and more, U.S. language researchers turned their attention to compiling data of English usage and Indian languages and to developing theories of grammatical structure.

Antebellum Linguistics

After 1819 a new generation of philologists and ethnographers investigated Indian languages in North America and used their research to reconfigure comparative grammar and linguistic typological-historical studies. In the United States, philologists and ethnographers debated genetic, structural, and evolutionary approaches to language typology, chiefly with regard to Indian languages and linguistic relativism.

American Indian languages

A year after Sir William Jones's famous 'Third anniversary discourse to the Asiatic Society of Calcutta' (1786), Jonathan Edwards (d. 1801), an amateur language observer, addressed the Connecticut Society of Arts and Sciences and argued that comparative analysis of vocabulary showed that the languages of the Delaware, Ojibwa, and Mohegans were genetically related: "It is not to be supposed, that the like coincidence is extended to all the words of those languages. Very many words are totally different. Still the analogy is such as is sufficient to show, that they are mere dialects of the same original language" (1787). Like Jones, Edwards proposed that language typologies be revised according to lexical comparative analysis. It was decades, however, before U.S. linguists took up Edwards's insight and constructed better accounts of the genetic and historical relations among languages and peoples.

Just as Europeans sometimes labeled American English as barbarous, so they sometimes referred to Indian languages as primitive, simple, or barbaric speech, simultaneously idealizing and infantilizing Indian languages and speakers. But North Americans' close association with Indians offered more linguistically sophisticated views of indigenous languages. As noted earlier, Roger Williams and Edward Winslow had regarded Algonkian languages as complex and copious. Benjamin Barton's (1766–1815) *New views*

on the origins of the tribes and nations of America (1797) used wordlists compiled by Williams, David Zeisberger, and others to posit (incorrectly) a genetic relation between Cherokee and Iroquois. Barton specifically used his comparisons to criticize European dictionaries and comparative grammars for lacking any real knowledge of or acquaintance with Indian languages.

In 1819, John Heckewelder (1743–1823) published his important *Account of the history, manners, and customs of the Indian nations, who once inhabited Pennsylvania and the neighboring states*, based on observations while living with the Delaware. In the chapter 'Languages,' Heckewelder laid the groundwork for a more detailed account of the genetic relations among Indian languages. He claimed that Delaware was a kind of "universal language, so much admired and so generally spoken by the Indian nations." Heckewelder, echoing Williams, wrote that "the Indians are not so poor, so devoid of variety of expression, so inadequate to the communication even of abstract ideas, or in a word, so *barbarous*, as had been generally imagined" (1819). He analyzed Delaware vocabulary and grammar in detail, while lamenting the lack of an adequate notation system for transcribing Indian languages. (In 1820, John Pickering did try to develop such an alphabet for Indian languages, *An essay on a uniform orthography* . . ., but his project foundered because he based his notation system on the Roman alphabet and European vowel values.) Linking language and cultural politics, Heckewelder idealized Indian culture and behaviors as purer and more authentically human when compared with the corrupted languages and behaviors of contemporary white societies.

Within the discourse of comparative philology, American antebellum philologists and ethnographers used their analysis of Indian languages to augment typological categories and reconfigure the discipline of linguistics. The most important heirs to Heckewelder's project were Pierre-Etienne [Peter Stephen] Duponceau (*see* **Duponceau, Pierre Etienne (1760–1844)**), John Pickering, and in their fieldwork, Albert Gallatin and Henry Schoolcraft. These scholars debated theory and method in philology and linguistics, in particular whether comparative analysis should focus on vocabulary or grammar. In his programmatic essay, 'Philology' (*Encyclopedia Americana* , 1830), Duponceau subdivided the discipline into phonology, etymology (language history), and ideology (grammar) (Robins 1987). Vocabulary, he argued, is not sufficient to show all the genetic (etymological) relations among languages, nor are word histories necessarily the most interesting aspect of language study from the universal rationalist perspective. A true philology would be "a science as vast in its extent as interesting in its details" and "requires to be subjected to some methodical order, in order that a comprehensive view may be taken of its whole extent, and a regular system pursued in the study of its component parts." In the first half of the 19th century U.S. linguists were concerned not only with data collection and typology but also with metatheoretical questions of philology and linguistics and with establishing a particularly American version of Germanic philology distinct from British language study.

Duponceau was a gentleman scholar and lawyer who immigrated to the United States in 1777. His linguistic writings focused on English and Indian languages, especially Algonkian. His first published linguistics paper, 'English Phonology' (1818) emphasized the variety of English dialect pronunciations worldwide and contrasted English pronunciation with other languages, including Indian languages. Duponceau framed U.S. English within the context of North American languages when he began by noting the distinctive *W* sound ("a soft whistling") in Lenni-Lenape and its syllable constraint: "[*W*] is a consonant, the sound of which is produced by a soft whistling; however barbarous this sound may appear to one who has never heard it, when pronounced, or rather whistled has a pleasing and delicate effect on the ear, although it is frequently followed by the consonant *d* or *t*, as in *Wdanis*, daughter, *Wtehim*, Strawberries, *Wtellsin*, to do so, &c." (Duponceau, 1818).

Duponceau also advanced general linguistic hypotheses and metaterminology. He identified the synchronic study of language sounds as "the curious and interesting science, which, until a better name can be devised, I would denominate the *Phonology of Language*" (1818). With his synchronic approach to phonology, he tried developing an "alphabet of sounds" to transcribe the speech of any language, and he gave new arbitrary names to seven English vowels (*aulif, arpeth, airish, azim, elim, oreb, oomin*). In language typology, Duponceau added the category *polysynthetic* to the existing matrix of morphological forms (*analytic*, *synthetic*, *agglutinating*) to better identify the morphology characteristic of Indian languages. In polysynthetic languages, "words can be compounded to any extent," so that "the languages [are] essentially polysyllabic, and . . . monosyllables are rarely to be found" (1832). Unlike Benjamin Barton (*New views on the origins of the tribes and nations of America*, 1797), Duponceau wrote that Indian languages display "a wonderful organization which distinguishes the languages of the aborigines of this country from all other

idioms of the known world." He added that language typologies should be based on grammatical, not lexical, comparisons, "those comprehensive grammatical forms which appear to prevail with little variation among the aboriginal native of America, from Greenland to Cape Horn" (1819).

John Pickering also did extensive comparative work on ancient and classical languages (he declined offers of the chairs of Hebrew and Greek at Harvard University) and on Americanisms, Indian languages (Cherokee), and South Pacific languages. He corresponded and debated with Webster, Duponceau, Bopp, Humboldt, and others on linguistic matters, and he contributed foundational arguments for a new 'science' of philology, based on German models for scholarship.

While something of a prescriptivist, especially in his early discussions of American English (*A vocabulary or collection of words*, 1816), most of Pickering's linguistic work was based on the humanist principle that the study of human beings in their social, cultural, and historical contexts should be taken up "through the medium of his [*sic*] noblest and peculiar faculty of speech" (1819). Pickering grafted this humanist ideal of language onto the 19th century's rationalist principle for language study and the development of "a *new science*," "the *comparative science of languages*." Applying models of German comparative philology and historical-typological grammar to the study of U.S. languages, Pickering sharply criticized Webster's lexicography and etymology for what he called the dictionary maker's weak scholarship (i.e., his amateurism) and for his use of Horne Tooke-style 'Saxon' analyses: "the works of the modern German scholars rise to a still higher degree of importance; and yet, strange to tell, none of the philologists in England [i.e., Tooke and his followers], or in our own country, appear to have derived any benefit from them. To judge from the labor of lexicographers in our language, the reader would hardly know that such men as Adelung . . . Humboldt, Grimm, Bopp, Rask, and others, of our own times, ever existed" (1837; Read, 1966).

In his 'Indian languages of America' (*Encyclopedia Americana*, 1830–1831), Pickering criticized previous European linguistic studies (notably Humboldt's) for not directly comparing Indo-European languages with Indian languages and for asserting without good evidence that Indian languages did not possess "genuine grammatical forms." His article focused primarily on the grammar of Cherokee verbs and reprinted Sequoyah's Cherokee syllabary, first developed in 1821. Pickering was the first European linguist to identify Cherokee's *inclusive* and *exclusive* plural pronouns prefixed to verbs (*in-*, I and you/we; *s-d-*, you two [not speaker], *o-s-d-*, I and another/we) (1830–31; cf. Pickering's annotated edition of John Eliot's [1666] *The Indian grammar begun*, 1822).

Pickering's contemporary, Albert Gallatin (1761–1849), was instrumental in the development of early American comparative linguistics and in the formation of linguistics as a profession. He helped establish the American Ethnological Society (1842, later the Anthropological Society of New York); he was founding president of the New York Historical Society (1843). Methodologically, Gallatin emphasized genetic, historical (etymological) relations and lexical comparisons among languages, especially Indian languages. But unlike Duponceau and Pickering, Gallatin had a more negative view of Indian peoples, calling them 'Savage Tribes.'

Gallatin's "A Synopsis of the Indian Tribes of North America" (1836) deployed a Humboltian-evolutionary approach to language change and vocabulary, but he adopted a more uniformitarian theory of grammatical processes as "natural causes," "resorted to in the most ancient times by other nations." Gallatin theoretically distinguished the lexicon, whose expansion marks the "great progress of knowledge," from grammatical forms, whose processes remain relatively constant (uniform) from the earliest state of a language to the present. Gallatin's wordlists for Indian languages were important resources for later ethnographers and field linguists.

By 1848 Gallatin had developed an important taxonomy of 32 distinct families of North American Indian languages (Introduction to *Hale's Indians of North-West America, and vocabularies of North America*), based on genetic relations among vocabulary alone. Revising his 1836 uniformitarian theory, he argued that some Indian languages' vocabularies "abound in distinct names for every particular species of tree, for every variety of age, sex, or peculiarity, in certain species of animals, and in degrees of consanguinity" (1848). Gallatin thus offered an early argument for the *advanced* cultural state of seemingly *primitive* peoples, based on comparisons of linguistic taxonomies and conceptual categories. But Gallatin's semantic analyses clashed with his evolutionary account of human cultures, where he described Indian tribes as historically and culturally more primitive than European or Asian cultures.

Henry Schoolcraft (1793–1864) linked the study of Indian languages' vocabulary with a national language project. "American speech," Schoolcraft argued, should reflect the diversity of languages in the United States, principally English and Indian languages. Like Lewis and Clark's expedition and James Fenimore Cooper's fiction, Schoolcraft's

linguistics linked Indian names and physical geography in American consciousness: "there is nothing in the geography of America, which impresses the observer more than the Indian names" (1827). Schoolcraft proposed that wherever possible in New York City original Indian names should be restored or replace those 'foreign' names imposed by colonists, none of whom could claim to be 'national' (1860). Schoolcraft hoped that the United States' growing independence from British political and linguistic domination would be the beginning of a new awareness of Indian languages and an opportunity to construct a more multicultural America by blending English and Indian naming practices. However, Schoolcraft's dream of a proactive study of North American Indian languages disappeared with the ascendance of Manifest Destiny (1845) and its Anglo-Euro racial focus.

The writings of Heckewelder, Pickering, Duponceau, Gallatin, and Schoolcraft map out the principal threads of typological and comparative-historical linguistics in the United States from 1815 to 1860. Their research dovetailed with popular autobiographies and narratives of Spanish and Indian languages and cultures and accounts of frontier speech (e.g., George Ruxton's *Life in the far west among the Indians and the mountain men 1846–47* [1849]). Through their fieldwork and grammatical and lexical analyses of Indian languages, Heckewelder, Gallatin, and Schoolcraft challenged European philologists' claims that Indo-European language categories are the only cognitive tools for organizing knowledge of a complex world and that Indians are 'primitive' because their languages lack such terms. Their data collection also provided key information to support a general theory of linguistic relativity. Duponceau and Pickering adopted German models of comparative philology as a counter to British linguistic ideas and used the grammars of Indian languages to expand the metadiscourse of language 'science.'

Around 1842: Global Linguistic Relativism

The year 1842 was a major turning point in the history of U.S. linguistics (Andresen, 1990). U.S. research on Indian languages motivated the foundation of the first professional linguistic society in North America, the American Oriental Society (1842), and its *Journal of the American Oriental Society* (1849). By 1842 Francis Lieber had completed the first edition of the *Encyclopedia Americana*, and the study of world languages was considered the foundation of the discipline of a scientific philology. Shortly afterward, in the summer of 1845, war with Mexico loomed (1846–1848) and the phrase Manifest Destiny created a public name for the national ideology that the United States was entitled to become a nation of predominantly white Europeans from the Atlantic to the Pacific.

In his presidential address at the founding of the American Oriental Society, Pickering outlined the scheme for American linguistics for the next 50 years. Philology, he said, is "a science, comparatively, of recent date, and the ultimate results of which, in ascertaining the relationship and history of nations – even of those which are not known to have ever had *written* languages – can hardly yet be justly appreciated" (1842/1849). Pickering argued the society's goal should be "to extend our inquiries beyond the Eastern *Continent* to the uncivilized nations, who inhabit the different groups of islands in the Indian and Pacific Oceans, from the eastern coast of Asia to the western coast of America; comprising that region of the globe which has been called Polynesia" (1842/1849). Pickering's global research program emphasized vocabulary and grammar as evidence for structural typology and genetic relations among languages.

As Pickering addressed his colleagues, the U.S. Exploring Expedition of 1838–1842 was concluding its voyages to South America and the South Pacific. The expedition's ethnographer and philologist was a 19-year-old Harvard student, Horatio Hale, recommended by Pickering and Duponceau (Mackert, 1994). The expedition's goal was to compile data of human diversity and experience. Following evolutionary (Humboldt) and American Indian languages studies, the organizers regarded language as a key to the migrations and genetic connections among peoples. Duponceau explained to Congress that the philologist should analyze languages "as to the words of which they are composed" and "as to their Structure or Grammatical Forms" (1836). Both Pickering and Duponceau believed that the tasks of the ethnographer and the philologist overlapped, and the U.S. Exploring Expedition implemented their disciplinary and theoretical views.

Hale published the results of his study of the peoples and languages of the North American Northwest Coast, Polynesia, South Pacific Islands, and Australia with the title *Ethnography and Philology* (1846). He modified Pickering's phonetic alphabet to transcribe languages and included research on migrations, trade languages, and grammars and vocabularies of Austronesian, Australian, and Northwest Amerindian languages. The U.S. Exploring Expedition and Hale's study foregrounded U.S. linguistics as a worldwide intellectual endeavor, as Webster and Pickering envisioned, and aligned the study of Indian languages with those of the Pacific Rim. After the expedition and publication of his *Ethnography and*

Philology, Hale did no ethnographic or linguistic work until the mid 1870s, when he concentrated on Iroquois and supervised Franz Boas's early fieldwork on the Northwest American coast.

Though not well known, Francis (Franz) Lieber's (1800–1872) work also focused on theories of linguistic relativity and the professionalization of linguistics. Born in Berlin, Lieber immigrated to the United States in 1827. He held academic posts at South Carolina College and Columbia College (New York City) and published widely on international law and political hermeneutics. Lieber's research and writing on language mark one of the earliest influences of the new German scholarship on U.S. linguistics.

Lieber edited the *Encyclopedia Americana* (1829–33), modeled on German scholarly lexicons. He wrote many of the articles and also enlisted Duponceau, Pickering, and others as contributors. Pickering certainly wrote the article 'Americanisms,' though it is unsigned, and Duponceau probably wrote 'Language' and 'Philology' (Andresen, 1990; Robins, 1987). The article 'Language' curiously defines *language* as "God-given" but a few pages later gives a more functional definition based on linguistic relativity: "Languages were made for the purpose of communication between men, and all are adequate to that end" (1830/1831).

Many of Lieber's published writings elaborate on linguistic relativity. In 'On the study of foreign languages' (1837) he compares different languages (Greek, Latin, French, German, English, Mohegan) to show their different cognitive and semantic structures: "These interesting inquiries into the division of ideas, and the difference of this division in different languages, by which we discover a different affinity and affiliation of thoughts and notions, a different perception of things, and a consequently different ramification of ideas; in short, a different logic of nations, may be continued without end" (1880/1837). Lieber contrasted Mohegan *holophrasis*, "words which express a complex of ideas" or "words which express the whole thing or idea, undivided, unanalyzed," with other languages' *polyphrasis*. Aesthetically, Lieber argued, holophrastic words display the "energy of style" which poets desire, thus ideologically linking Indian languages with heightened creativity. Later, Sapir compared Algonquian languages' words formed through polysynthesis to "tiny imagist poems."

Lieber developed his analysis of holophrasis in Indian languages in his "Plan of thought of the American languages" (1851–1857), included in Schoolcraft's *Archives of aboriginal knowledge* (1860). But when Lieber contrasted polysynthetic Indian languages, principally Mohegan, with analytic languages such as French, his linguistic relativism became evolutionary: "as man begins with *perceiving* totalities, and then generalized in his *mind*, so do children and early nations show the strongest tendency to form and use . . . *bunch words*" (1860). In Lieber's structural typology, linguistic relativism competes with linguistic evolutionary anthropology.

Lieber's 'Vocal Sounds of Laura Bridgman' (1850) reports on his case study of a child rendered blind and deaf by scarlet fever. Bridgman was the first U.S. deaf-blind child known to have been educated to speak and use visible language; she read and communicated with fluent finger spelling (Davis). Lieber outlined the sixty vocal sounds Bridgman used as names for people she knew well and their phonetic features (monosyllabic, mostly labial). But archival research shows that Lieber never published his much larger work on Laura Bridgman, in which he analyzed her communication in a broad linguistic-semiotic context (Davis). In the unpublished work, composed as nine letters to his son Oscar, Lieber reported on Bridgman's post-illness language acquisition and what it suggests about human language and cognition. For example, Lieber argued that Bridgman did not have access to the largely unconscious modes by which hearing-sighted people acquire words' nuances of meaning, tone, and context. Analysis and abstract words, he theorized, are part of higher cognition acquired through ordinary speech.

Most of Lieber's writing on linguistic topics remains unpublished, including work on Indian languages, American–British English divergence, African American speech, linguistic relativism, sociolinguistics (pidginization, language contact, language change, code switching), and the important text on Laura Bridgman's acquisition of signed English (see *Notes on language,* 10 volumes, Huntington Library, San Marino, CA). For Lieber, language is an arbitrary system of signs, organized by hearing and nonhearing users primarily to communicate information and exchange ideas, impressions, and desires. Language, he wrote, is organized by general laws and comprised of sensuous material (sound). In several works Lieber contrasted languages according to his holophrastic-paraphrastic typology. Lieber's linguistic relativism and theory of language as a sign system were themes later developed by Charles S. Peirce, William Whitney, Edward Sapir, Roman Jakobson, and modern semioticians.

The Beginnings: Noah Webster

Before and for some decades after the American Revolution, British dictionaries (particularly that of Samuel Johnson) were used in the United States, usually in pirated form. The first dictionary produced by an American was *A school dictionary* (1798) by Samuel Johnson, Jr. (not related to the great English lexicographer). This dictionary was short and had only brief (and often flawed) definitions that were considered appropriate for students. Its pronunciation system was inadequate even by the standards of the time (as Johnson himself acknowledged), and it included no Americanisms. About all that can be said for it is that it existed, as the first natively produced dictionary in the United States. The pirated British dictionaries were sometimes better, but their coverage of American English was haphazard. They had occasional but irregular American spelling variants but few genuinely American terms. American English was not recognized as a separate regional standard of English. All this changed with Noah Webster (1758–1843).

Noah Webster began his lexicographic career in 1783 with the publication of the *American spelling book*, also known as *The blue-backed spelling book*. This phenomenally popular work went through many editions and hundreds of printings during Webster's lifetime, and by the end of the 19th century it had sold an estimated 100 million copies. Webster's efforts to combat piracy had an influence on the establishment of federal copyright laws in 1790. In contrast to the exclusively religious leanings of earlier works, the *Spelling book* was marked by a strong patriotic and moral tenor: "A good child will not lie, swear, nor steal," went a typical reading passage, "He will be good at home, and ask to read his book; when he gets up he will wash his hands and face clean." Its spellings adhered to a British model, but in subsequent works Webster changed his mind and argued in favor of spelling reform. He thought deeply about spelling throughout his life, and in mid-life he advocated more radical reforms than those that he eventually adopted in his major dictionaries.

Webster's first dictionary was *A compendious dictionary of the English language* (1806). Less important than his later works, it nonetheless included

is that it shows how corpus evidence can be linked to linguistic theory. The field is wide open for a new initiative, inspired by such developments, that will take advantage of computer technology, corpus linguistics, and cognitive linguistics to create an empirically well-founded, corpus-based study of current American English usage, showing how each word in the language is used and how the meanings are related to usage.

Introductory Remarks

Amharic (self-name *amariṇṇa*) is the largest member of the South Ethiopic branch of Ethiopian Semitic languages. Amharic is spoken, according to the most recent estimate (1999), by around 17.4 million people as a first language and between 5 and 7 million more as a second language, making it the second largest Semitic language after Arabic, and the fourth largest language of sub-Saharan Africa after Swahili, Hausa, and Yoruba, although some estimates suggest that Oromo may have more speakers in total. Amharic is the main lingua franca of Ethiopia and is the constitutionally recognized working language of the country. As such it forms the language of instruction of public education at primary and secondary level, including from the third grade upwards in areas where it is not the first language. It is also the majority language of most urban-dwelling Ethiopians except where Tigrinya (Tigrigna) is the first language. The current status and wide distribution of Amharic are due especially to the amharization policies of previous Ethiopian governments in the 20th century. Until the change in language policy after the Ethiopian revolution of 1974, Amharic was the only Ethiopian language used in state education and the official media. The earliest records of Amharic date to the rise of the Amhara or Solomonid dynasty in the 14th century, and the spread of the language over an ever-increasing area of the Ethiopian highlands accompanied the expansion of the Christian kingdom up to modern times.

Modern Amharic shows some dialectal variation, though perhaps less than might be supposed for a language with such a wide distribution. This may in fact be due to the way in which the language has spread over the last 700 years, as part of a deliberate process of amharization, and it is notable to this extent that the dialect areas that are generally

recognized are geographically defined within the regions where Amharic either originated or has been spoken the longest. The dialect of Shoa and, in particular, Addis Ababa has become the prestige dialect, forming a *de facto* standard. This is the form of Amharic that is used in the media as well as in the areas of administration and education.

Like all the modern Ethiopian Semitic languages, Amharic has been heavily influenced by the Cushitic languages alongside which it has developed, initially the now minority Central Cushitic languages and then, as it spread, Highland East Cushitic and later Oromo. This influence can be seen not only in the lexicon, but also in syntax and typology. As the language of the ruling elite and thus the inheritors of Ethiopian Christian culture from Aksum, Amharic was also open to borrowing from Geez, the classical or liturgical language of the Ethiopian Orthodox Church, which in more recent times has provided a rich source for the expansion of the Amharic lexicon to satisfy the need for technical, political, and other vocabulary.

Amharic is written in the Ethiopic syllabary, the script used for Geez and developed in Ethiopia probably sometime during the 4th century C.E. out of the South Arabian consonantal alphabet. The Ethiopic syllabary, or *fidäl*, used for Amharic has 33 primary symbols, which indicate C + vowel /ɐ/, each of which is further modified in some way to indicate C + one of the remaining six vowels: በ /bɐ/, ቡ /bu/, ቢ /bi/, ባ /ba/, ቤ /be/, ብ /bɨ/, ቦ /bo/, in the traditional sequence, giving 231 basic letters. Whilst some of the modifications are more or less regular across the whole system, others are not. For instance C + vowel /e/ is always marked by a loop attached to the bottom right-hand of the basic letter, but there are 16 different ways of marking C + vowel /ɨ/. The whole structure is traditionally displayed in a grid with consonants on the vertical axis and vowels on the horizontal. The sixth column of the grid indicates both C + vowel /ɨ/ and C without a following vowel: ብ = both /bɨ/ and /b/. The contrast between C + /ɐ/ and C + /a/ is mostly neutralized where C is a guttural /ʔ/ or /h/: graphemes ሀ {hɐ} and ሃ {ha} are both /ha/. Whilst there are 33 base letters, these correspond to 27 consonant phonemes, as there is a certain amount of redundancy: for example, the letters ሀ, ሐ, ኀ, and ኸ all mark the consonant /h/; ኧ and ዐ mark a lack of consonantal onset, or /ʔ/ depending on analysis. The labialized gutturals /kʷ/, /gʷ/, /k'ʷ/, and /hʷ/ are indicated by additional vowel symbols attached to the corresponding nonlabialized consonant signs: ቍ = /k'ɐ/, ቋ = /k'ʷɐ/. In addition to these, a number of other consonant bases have a special symbol for C + /wa/: ጕ = /dʒɐ/, ጓ = /dʒwa/. There is lastly one other place where the Ethiopic syllabary does not correspond exactly to the phonemic structure of the language; consonantal length is phonemic in Amharic but is not marked at all in the script: thus /alɐ/ 'he said' and /allɐ/ 'there is' are both written አለ, i.e., {ʔa} + {lɐ}. As an example of a piece of continuous text, consider the following, which is the last example cited in this article:

ይህ ነገር ብዙ ጊዜ ስለሚያስፈልግ አስከ
ምሽት ነው መሥሪያ ቤት የሚቆዩት ።
{jɨ + hɨ nɐ + gɐ + rɨ bɨ + zu gi + ze
sɨ + lɐ + mi + ja + sɨ + fɐ + lɨ + gɨ ʔt + sɨ + kɐ
mɨ + ʃɐ + tɨ nɐ + wɨ mɐ + sɨ + ri + ja be + tɨ
jɐ + mi + k'ʷɐ + ju + tɨ}
/jɨh nɐgɐr bɨzu gize sɨlɐmmijasfɐllɨg ɨskɐ mɨʃʃɐt dɨrɐs
nɐw mɐsrija bet jɐmmik' ojjut/
'because this thing needs a lot of time, they'll stay
behind at work until evening'

Phonology

Amharic has a system of 30 consonant (see Table 1) and 7 vowel phonemes. Distinctive are the glottalized consonants, which have parallels in other languages of the Ethiopian language area. Also notable are the labialized gutturals /kʷ/, /k'ʷ/, /gʷ/, and /hʷ/; indeed, labialization of other consonants occurs, but only before the vowel /a/, and is contrastive as for instance in the nearly minimal pair /mʷ atʃ/ 'deceased' – /mɐtʃe/, /mɐtʃ/ 'when?' The addition of phonemic units such as /mʷ/ would increase the number of consonant phonemes. Consonant length is also phonemic; only /h/ and the glottal stop, whose phonemic status in Amharic is debatable, do not have lengthened counterparts. The vowel system is distinguished by the presence of two central vowels, high /ɨ/ and low-mid /ɐ/, which together with low /a/ are the most frequent vowels in the language. Vowel length is not phonemic.

Table 1 The consonant phonemes of Amharic

	bilabial	*alveolar/ dental*	*palatal*	*velar*	*glottal*
Plosive/affricate	b p	d t	dʒ tʃ	g k	(/ʔ/)
Glottalized plosive/ affricate/ fricative	p'	t'	tʃ' s'	k'	
Labialized			gʷ kʷ k'ʷ		hʷ
Fricative	f	z s	ʒ ʃ		h
Nasal	m	n	ɲ		
Lateral		l r			
Approximant	w		j		

The vowels of Amharic are /i/, /ɨ/, /u/, /e/, /o/, /ɐ/, and /a/. The phonemic status of the vowel /ɨ/ has been the matter of some discussion, and certainly its occurrence as a default epenthetic vowel in the application of syllable structure rules is predictable: the consonantal strings/s-n-t/, /m-l-kk-t/being resolvable only as /sɨnt/ 'how much?' and /mɨlɨkkɨt/ 'sign,' respectively. Contrast /d-n-g-l/, which surfaces predictably as /dɨngɨl/ 'virgin.' Indeed, the Ethiopic syllabary uses the same set of symbols for a consonant alone and a consonant + /ɨ/. However, forms such as /jɨs'ɨfall/ 'he writes' rather than the predicted /*jɨs'fall/ indicate that /ɨ/ does have phonemic status.

Ethiopianist convention occasionally employs different symbols from the IPA ones used here; thus, š = ʃ, ž = ʒ, č = tʃ, q = k', ṭ = t', č̣ = tʃ', ǧ = dʒ, ṣ = s', p̣ = p', ñ = ɲ, y = j, ä = ɐ, ə = ɨ.

Syllable structure is [C]V[C][C], with no more than one consonant permitted in syllable onset position, and no more than two in syllable coda or, indeed, word medially and finally, with a lengthened consonant counting as two, as in the example of /mɨlɨkkɨt/ above.

Accent in Amharic has been the subject of only a few studies, and its nature is still somewhat a matter of discussion. Generally, whilst Amharic accent is essentially a weak stress accent, it seems that word accent is subordinate to phrasal or sentence accent.

Morphology

Amharic has a complex inflectional morphology, particularly in the verbal system, employing not only prefixes and suffixes but also internal modification of the typical Semitic consonantal root-and-pattern type. In general, the morphology of Amharic has been less influenced by the Cushitic substratum than, for instance, syntax or the lexicon. The inflectional morphology of nouns, on the other hand, is relatively simple. Like other South Ethiopic languages, Amharic has mostly lost the heterogeneous system of noun plural formation by internal modification, the so-called broken plurals that are so common in North Ethiopic languages such as Geez and Tigrinya, and in some other Semitic languages such as Arabic. Noun plurals in Amharic are for the most part formed by means of the suffix /-otʃtʃ/. Nouns also show two genders, though these are mostly manifest only in concord, chiefly between subject and verb predicate. Nouns further show definite marking by means of suffixes: masc. /-u/~/-w/ and fem. /-wa/, which are in origin 3rd person pronominal suffixes: /bet-u/ is thus both 'the house' and 'his house.' Amharic does not have a true case system, adverbial functions being expressed variously by prepositions, or postpositions, or interestingly by a combination of the two: /kɐ-sɐwɨjje-w gar/ 'with the man,' where /kɐ-/ and /gar/ together gloss 'with.' Of the primary relational case functions, the subject is unmarked, a definite direct object is usually marked by the clitic /-n/, which occurs after the marker of definiteness within the noun phrase, and the possessive or adjunct function is indicated by the bound preposition /jɐ-/, which is in form and origin identical to the adjunct or relative marker on verbs:

leba	jɐ-gɐbɐre-w-n	lam	sɐrrɐk'-ɐ
thief	*of-farmer-DEF-OBJ*	*cow*	*steal.PAST-3MASC.PAST*

'a thief stole the farmer's cow'

abbat-e	gomɐn-u-n	b-atakɨlt	bota	zɐrra-[Ø]
father-my	*cabbage-DEF-OBJ*	*in-vegetable*	*place*	*sow.PAST-[3MASC.PAST]*

'my father sowed the cabbages in the garden'

The verb is inflected for voice or valency, tense–mood–aspect (TMA), and person. Negation is also marked within the inflected verb, as is to a large extent the distinction between main and subordinate verbs. In addition to the base stem, typically with active function, there are three fundamental voices or derived stems formed by prefixes: causative /a-/, passive-reflexive /tɐ-/, and factitive or (double) causative /as-/. There are other less productive formatives of more restricted occurrence, such as /astɐ-/, which also has a causative function, and /an-/ and /tɐn-/, with transitive-causative and stative-passive functions on verbs with expressive meaning (movement, sound, emotion, etc.). Internal changes in the various formations of TMA stems, however, combine with these prefix formatives and sometimes obscure them: /tɐ-sɐrrɐk'-ɐ/ 'it was stolen' but /jɨ-ssɐrrɐk'-all/ 'it will be stolen,' where the imperfective or nonpast stem corresponding to /tɐsɐrrɐk'-/ is /-ssɐrrɐk'-/. The occurrence of derived stem formatives is also to some extent lexical: /tɐ-k'ɐmmɐt'-ɐ/ 'he sat down' is active and does not contrast with a base stem /*k'ɐmmɐt'-/.

Other derived stem patterns involve internal modification such as a change of vocalization, or reduplication of syllables, often in combination with the prefixes described above: /a-nnɐgaggɐr-u/ 'they engaged one another in conversation' from the basic /nɐggɐr-u/ 'they spoke.'

TMA marking is done by internal changes in the verb stem together with variations in person marking. Most notable here is the use of one set of personal suffixes for the past in contrast to a quite different set of prefixes, or prefixes and suffixes combined, for the nonpast stem: /wɐddɐk'-ɐtʃtʃ/ 'she fell' but /tɨ-wɐdk'-all-ɐtʃtʃ/ 'she falls, is falling,' /a-t-wɐdk'-ɨmm/ 'she isn't falling,' /tɨ-wdɐk'/ 'let her fall,' /bɨ-t-wɐdk'/ 'if she falls,' etc., where the stems are past /wɐddɐk'-/,

nonpast /-wɐdk'-/, and jussive-imperative /-wdɐk'-/, and the person markers for the 3rd feminine are past /-ɐtʃtʃ/, nonpast and jussive/t[ɨ]-/, and the other elements are variously /-all-/ main verb affirmative nonpast, /a- . . . -[ɨ]mm/ main verb negative nonpast, and /b[ɨ]-/ 'if.'

In addition to subordinate verbs formed by prefixes such as the conditional formative above, Amharic also possesses an inflected all-purpose adverbial subordinate verb, called the gerundive in much of the literature, though the term 'converb' (CONVB), which is occasionally used, is a better label: /wɐdk'-a/ 'she having fallen,' but from /sɐmma-tʃtʃ/ 'she heard' /sɐmt-a/ 'she having heard.' The gerundive/converb is typically used in describing a sequence of events:

ɨnnantɐ ɨzzih k'ɐrt-atʃtʃɨhu zɨmm
you.PL here remain.CONVB-2PL 'quiet'
bɨl-atʃtʃɨhu tɐ-k'ɐmɐt'-u
say.CONVB-2PL sit.IMP-PL
'you, stay here and sit quietly' ('. . . being quiet')

t'ɐlat ʃɐʃt-o tɐmɐllɐs-ɨn
enemy flee.CONVB-3MASC return.PAST-1PL
'they enemy fled and so we returned'

The gerundive/converb in combination with the main verb marker (MVM) /-all/, etc., also forms the basis of a second past tense main verb form which generally indicates a recent past event or situation resulting from a past event: /alk'-o-all/>/alk'^{w}all/ 'it is finished.'

The formal distinction between main and subordinate verb forms is not carried through the whole TMA system. The past tense form, such as /wɐddɐk'-ɐ/ 'he fell' occurs in both positions and has no MVM as such, whilst the simple nonpast form /jɨ-wɐdk'/ 'he falls, will fall' occurs only in subordinate position, either with an auxiliary as in /jɨ-wɐdk' nɐbbɐr/ 'he was falling,' or more usually with a subordinating element: /jɐmm-i-wɐdk'/ '(he) who falls,' /s-i-wɐdk'/ 'when he falls/fell.' When used in main verb position, it requires the partially inflecting MVM if affirmative: /jɨ-wɐdk'-all/ 'he falls,' /tɨ-wɐdk'-all-ɐtʃtʃ/ 'she falls,' or the main verb form of the negative marker if negative: /a-j-wɐdk'-ɨmm/ 'he doesn't fall.'

In addition to the elements discussed so far, the verbal complex may also contain pronoun object markers. These are of two kinds, essentially direct object pronouns and pronominal object pronouns, which involve an element /-ll-/ or /-bb-/ clearly associated with the simple nominal prepositions /lɐ-/ 'to, for' and /bɐ-/ 'in, with':

ajt-ɐn-ɐw-all
see.CONVB-1PL-him-MVM
'we have seen him'

adrɨg-o-ll-ɨŋŋ-all
do.CONVB-3MASC-for-me-MVM
'he has done [it] for me'

Syntax

Word order in Amharic is generally subject-object-verb (SOV), with subordinate clauses preceding the main clause. Noun phrases are also generally head final with modifiers, including relative clauses, preceding the noun. Whilst a large part of Amharic syntax is influenced by Cushitic language patterns and is in accord with the typology of verb-final languages, there are still structures such as prepositions alongside postpositions which betray the older 'classical' Semitic syntax. Like most languages of the Ethiopian language area, Amharic makes considerable use of focus marking, which is here expressed by a construction involving the copula, which 'highlights' the focused item, and the relative verb, the so-called cleft clause construction:

zɐmɐd-otʃtʃ-wa n-atʃtʃɐw bal
relative-PL-her COP-3PL husband
jɐ-mɐrrɐt'-u-ll-at
REL-choose.PAST-3PL-for-her
'it is her relatives who have chosen a husband for her'

jɨh nɐgɐr bɨzu gize
this thing much time
sɨlɐ-mm-ij-asfɐllɨg
because-REL-3MASC-need.NONPAST
ɨskɐ mɨʃʃɐt dɨrɐs n-ɐw mɐsriya-bet
until evening until COP-3MASC work-place
jɐmm-i-k'ojj-u-t
REL.NONPAST-3(PL)-stay.NONPAST-PL-DEF
'because this thing needs a lot of time, it's until evening that they'll stay behind at work'

Amman, Johann Conrad (1669–1730)

J Noordegraaf, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Amman, who earned his reputation as a speech therapist and as a pioneer in the field of the teaching of the deaf and dumb, was a German-speaking Swiss. Born in Schaffhausen, he studied in Basel, where he graduated as a medical doctor in 1687. He moved to the Netherlands, where he did most of his work. First he settled in Amsterdam; later on he lived in Haarlem. He died in Warmond, near Leiden, in November 1724.

Having taught several pupils in Schaffhausen and Amsterdam to speak, Amman spent the years 1690–1692 engaged in the instruction of the daughter of a Haarlem merchant. His approach was described in *Surdus loquens* ('The talking deafman,' 1692), a work showing that Amman advocated spoken language as the most important means of communication for the deaf. In 1700 his *Dissertatio de loquela* appeared, a 'Dissertation on speech.' An extended and improved version of *Surdus loquens,* it had a more general phonetic basis than his previous work. Moreover, its preface contains some correspondence between Amman and John Wallis; their works have various points in common. Among Amman's other publications are translations of dialogues by Plato (1709) and of a contemporary medical work (1692); in cooperation with a Dutch classicist he edited the text of a 5th-century medical work (1704).

Amman's dissertations, in which important advances in describing the anatomy and physiology of the speech mechanism are made, are divided into three parts. Amman first deals with speech and voice in general, and subsequently expounds on the nature of the 'letters' and the various modes to form them. Finally, he explains how he taught his pupils to speak, viz. by making them familiar with the position and the movement of the lips, tongue, etc., that are specific to each vowel and consonant. Reflecting upon the process of articulation, Amman came to the conclusion that the large variability of sounds could in fact be reduced to 24 'letters,' a sort of natural alphabet that is common to all languages. Thus, an instructor could concentrate on the sounds that belong to this alphabet, abstaining from dialectal variants.

Amman made the acquaintance of the cabbalist F. M. van Helmont (1614–1699), who had witnessed his teachings at Haarlem. In 1667 van Helmont had published on an 'alphabet of nature,' a Dutch translation of which appeared in 1697, jointly with a Dutch version of *Surdus loquens*. This connection may explain some metaphysical notes in Amman's work.

Although his method remained virtually unnoticed in the Netherlands, Amman's ideas concerning the primacy of speech and speech reading were followed by Samuel Heinicke (1723–1790), the founder of the so-called German school. There was a difference of opinion between Heinicke and the French Abbé de l'Epée (1712–1789), who founded a school for the education of the deaf in Paris in 1760 based on sign language and the manual alphabet, a dispute that continued for more than a century. Be that as it may, today Amman is still considered one of the distinguished pioneers on the subject.

A-Morphous Morphology

S R Anderson, Yale University, New Haven, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

A-Morphous Morphology (Anderson, 1992) is a framework for the analysis of complex words (including inflection, derivation, compounding, and other types of word formation). It is a realizational framework in the sense that it sees morphology as establishing a many-to-many correspondence between aspects of a word's form and aspects of its content rather than as concatenating a series of purely local sound-meaning correspondences (morphemes). It is a lexicalist and postsyntactic view in that it maintains that the content and internal form of words are neither accessible to nor manipulated by principles of the syntax. The only interface between words and the syntax is an informationally minimal morphosyntactic representation, comparable in most respects to the complex symbols of Chomsky (1965).

The most distinctive aspect of this point of view is its rejection of the classical morpheme, traditionally the cornerstone of morphological analysis. Word structure is built up through modifications to a basic stem, including affixation as one among several formal possibilities. Once an affix is associated with a stem, however, the result is not presumed to have internal structure of a nonphonological sort. Some complex words (particularly compounds) generally **do** have such a structure, but the mere fact that a word's form is motivated in part by relations to other words does not in itself establish that.

Reasons to Reject the Classical Morpheme

The starting point of morphological analysis is what de Saussure referred to as the partially motivated sign, in which the relation between the form of a word and its (complex, analyzable) content can be decomposed into parts, some of which it shares with other words. Content here refers both to the lexical meaning of the word and to the morphosyntactic categories that influence its form. In sets of morphologically complex words, similarities of form correlate with similarities of meaning. For structuralist theory, these similarities inhere in structural units, morphemes, which have the character of Saussurean minimal signs. A morpheme is a "linguistic form which bears no partial phonetic-semantic resemblance to any other form" (Bloomfield, 1933: 161), or a "minimal same of form and meaning."

On that view, words are taken to be exhaustively analyzable into a sequence of such minimal signs or morphemes. Because the basis of the sign is the indissoluble unity of sound and meaning (and [morpho]-syntax), there should then be a one-to-one association between elements of form and elements of content. That is, every chunk of form ought to correspond to exactly one chunk of meaning, and vice versa. Only in unsystematic instances of accidental homophony or synonymy should we find exceptions to this.

In fact, however, the notion that the elemental building blocks of words can be discovered by looking for recurrent relations between form and meaning is falsified in both directions. One problem is the existence of phonæsthemes. In sets of words such as *glimmer, glitter, gleam, glow*, . . . ; *slide, slip, slither, slink, slippery*, . . . we find a shared aspect of meaning and a similarity of form, but (whatever the etymological source of such relations) speaker intuitions reject the notion that *glimmer*, for example, is composed of two elements, *gl-* and *-immer*, in the way *bookish* is composed of *book* and *-ish*. It will not do to say that only one of the parts here (presumably *gl-*) has a separable meaning because the same could be said for words such as *raspberry*, in which only the *-berry* part has a meaning apart from the combination but speakers do not hesitate to see the word as internally complex.

The other side of this coin is the existence of word-internal structure in which neither formal component of a complex word can be regarded as having distinct content. This is the case with sets of English verbs composed of a prefix and a stem (e.g., *deceive, receive, defer, refer*), neither of which makes a consistent contribution to the content of combinations including them (Aronoff, 1976).

Even ignoring such problems that arise when we attempt a parallel division of the form and content of

Analytic Philosophy

M Beaney, Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

'Analytic philosophy' is the name that is given to what is now generally regarded as the dominant philosophical tradition in the English-speaking world and increasingly in the rest of the world. In its widest sense, it might be taken to mean any kind of philosophy in which analysis plays a central role. But there are all sorts of kinds of analysis, and analysis – in one form or another – has been part of philosophy since the time of the ancient Greeks. Sometimes it is characterized in terms of the emphasis placed on clarity, rigor, and careful argumentation, often involving logical formalization. This might distinguish it from some types of 'continental' philosophy (as it is misleadingly called), to which analytic philosophy is frequently seen as opposed. But the best way to understand analytic philosophy is historically, as a movement that had its roots in developments around the turn of the 20th century and evolved in various directions in response to them.

The origins of analytic philosophy lie in the work of Gottlob Frege (1848–1925), Bertrand Russell (1872–1970), G. E. Moore (1873–1958), and Ludwig Wittgenstein (1889–1951). In many ways, early analytic philosophy can be seen as comprising two main strands, one developing from Frege's logical analyses of number statements and Russell's theory of descriptions, and the other from Moore's concern with conceptual analysis in ethics and epistemology, the two strands synthesised to some extent by Wittgenstein in the *Tractatus* (1921).

Frege's Analysis of Number Statements

Central to Frege's logical analysis of number statements is the idea that number statements are assertions about concepts. A statement such as *Jupiter has four moons* is to be understood, not as predicating of Jupiter the property of having four moons, but as predicating of the concept 'moon of Jupiter' the second-level property 'has four instances,' which can be logically defined (cf. Frege, 1884: § 57). The philosophical significance of this idea can be illustrated by taking the case of negative existential statements (number statements involving the number 0), which have caused problems throughout the history of philosophy. Consider the following statement:

(U) Unicorns do not exist.

This statement is true, so it must clearly have a meaning. But what is it for (U) to have a meaning? If we analyze it in subject-predicate terms, in accord with its surface grammatical form, then 'unicorns' is the subject and 'do not exist' the predicate. But how can we say anything meaningful if 'unicorns' does not refer to anything? If unicorns do not exist, then what is it to which we are predicating the property of nonexistence? Should we posit – as Meinong and the early Russell did – the 'subsistence' of nonexistent objects to act as the subjects of statements about them? On Frege's account, however, such a statement is to be understood as asserting something, not about unicorns but about the concept of 'unicorn.' (U), in other words, really means what is better expressed as:

(U*) The concept 'unicorn' is not instantiated.

Interpreted like this, it can then be readily formalized in modern logic:

(U#) $\neg \exists x\, Fx$.

On Frege's view, existence should not be seen as a (first-level) predicate, but instead, existential statements are to be analyzed in terms of the (second-level) predicate *is instantiated*, represented by the existential quantifier. To say that something does not exist is to say that the relevant concept is not instantiated.

Russell's Theory of Descriptions

A similar strategy is employed by Russell in his theory of descriptions (1905). Consider Russell's famous example:

(K) The present King of France is bald.

This too might tempt us to suppose that a king of France must somehow exist – or 'subsist' – in order to be the subject of such a statement. According to Russell, however, (K) is to be analyzed as (K*), which can then be formalized as (K#):

(K*) There is one and only one King of France, and whatever is King of France is bald.

(K#) $\exists x\ (Kx\ \&\ \forall y\ (Ky \rightarrow y = x)\ \&\ Bx)$.

Here there is no commitment implied to any nonexistent objects. All that is needed to understand the statement is a grasp of the relevant concepts and logical constants (including the quantifiers). Definite descriptions, such as 'The present King of France,' on Russell's view, are to be 'analyzed away': they do not have meaning in isolation (by standing for some object) but only in the context of the sentences in which they appear (sentences that have a complex, quantificational structure).

F. P. Ramsey called Russell's theory of descriptions a 'paradigm of philosophy' (1931: 263), a view shared by both Moore and Wittgenstein. As Wittgenstein put it in the *Tractatus* (1921: 4.0031): "It was Russell who performed the service of showing that the apparent logical form of a proposition need not be its real one." What both Frege's and Russell's logical analyses open up is a gap between grammatical (or apparent logical) form and (real) logical form. On the surface, both (U) and (K) seem to have a simple subject-predicate structure, but their underlying structure is more complex, revealed in (U#) and (K#). Generalizing, this suggests a whole program of analysis, the aim being to uncover the real logical form of the various statements we make, especially those that are philosophically significant or are liable to lead us astray. On Frege's and Russell's conception, then, analysis involves the rephrasing of problematic statements into 'correct' logical form.

Moore's Conception of Analysis

Although Moore and Russell are often closely associated, and Moore endorsed Ramsey's praise of Russell's theory of descriptions (Moore, 1959: 195), Moore was less concerned than either Frege or Russell with the development of a logical system as a means to 'correct' ordinary language. Like the early Russell, in his own early work Moore assumed a crude decompositional conception of analysis. Propositions, for the early Moore, were complex concepts, and their 'analysis' simply involved their decomposition into their constituent concepts. But alongside this decompositional conception was a looser conception of analysis as clarification. This comes out in *Principia ethica*, in which Moore talks of 'analysis' as involving the distinguishing of questions that are misleadingly conflated, remarking that "the more clearly distinct questions are distinguished, the better is our chance of answering [them] correctly" (1903: 27; cf. vii). His later work is characterized by the careful and detailed – indeed, pedantic – attention he pays to the subtle distinctions of ordinary language in an attempt to resolve certain traditional philosophical puzzles, such as the problem of the external world (Moore, 1959: chapter 7).

Wittgenstein's *Tractatus*

In the *Tractatus* (1921), Wittgenstein expresses his great debt to Frege and Russell but shares Moore's view that ordinary language is in perfect logical order as it is and does not need 'correcting' (cf. 1921: 5.5563). What was needed was not an ideal language but an ideal notation, revealing the underlying semantic structure of ordinary propositions no longer obscured by their surface syntactic form. The aim of analysis was to uncover the necessary presuppositions of our use and understanding of ordinary language. Notoriously, on Wittgenstein's early view, the logic of our language required the necessary existence of simple objects, a view he was later to repudiate as part of his general critique of the Tractarian picture theory of language and logical atomism.

Logical and Metaphysical Analysis

The early 1930s marked the heyday of the form of analysis embodied in Wittgenstein's *Tractatus*. During this period an important distinction came to be drawn between what was called 'logical' or 'same-level' analysis and 'metaphysical' or 'reductive' or 'directional' or 'new-level' analysis. The first translates the proposition to be analyzed into better logical form, while the second exhibits its metaphysical presuppositions. Take Russell's theory of descriptions again. In offering (K#) as the analysis of (K), the definite description is 'analyzed away': this is logical analysis, revealing the underlying structure of the statement. But once we have (K#), we must still explain the commitments that remain – to the relevant logical constants and concepts. This may in turn require further analysis to 'reduce' them to things of our supposed immediate acquaintance – such as the 'sense data' to which Russell himself appealed.

Ordinary Language Philosophy

During the 1930s, however, metaphysical analysis came under increasing fire, the assumptions of logical

atomism being found unsupportable – in particular, the commitment to such things as simple objects or sense data. But this still left logical analysis – combined now with conceptual or linguistic clarification rather than metaphysical reduction. Wittgenstein himself gave up the idea that Fregean logic provided 'the' logic of ordinary language, but he continued to explore the 'logic' – or what he now tended to call the 'grammar' – of our concepts. In this he influenced a whole generation of philosophers, particularly those dominant in Oxford during the 1950s and 1960s: Gilbert Ryle (1900–1976), J. L. Austin (1911–1960), Paul Grice (1913–1988), R. M. Hare (1919–), and Peter Strawson (1919–). Ryle, for example, explored what he called the 'logical geography' of our mental concepts in *The concept of mind* (1949), in which he introduced the important idea of a 'category-mistake.' According to Ryle, Descartes made a category-mistake in treating the mind as some kind of spiritual substance, in just the same way as a tourist who asks where Oxford University is in Oxford makes a category-mistake. Austin, even more than Moore, saw philosophical clarification as requiring close attention to the subtle nuances of ordinary language, and his distinction between locutionary, illocutionary, and perlocutionary acts played a key role in the creation of speech-act theory. Grice's conception of conversational implicature, too, might be singled out as influential in the development of speech-act theory and, more generally, in the recognition of the pragmatic alongside syntactic and semantic dimensions of language use.

Strawson is perhaps the best-known representative of the ordinary language movement in 20th-century philosophy. His critique of Russell's theory of descriptions in 'On referring' (1950) is as much a classic as Russell's original 1905 paper. Even though Strawson's *Individuals* (1959) marked a return to metaphysics, it was a form of metaphysics that Strawson called 'descriptive' rather than 'revisionary,' aimed at clarifying our basic conceptual frameworks. In a much later work (1992), Strawson talked of 'connective' rather than 'reductive' analysis as being the methodology of philosophy, illustrating just how far 'analytic' philosophy has evolved since the heyday of logical atomism.

Logical Positivism and the Quinean Tradition

But ordinary language philosophy, rooted in the work of Moore and Wittgenstein, represents only one wing of 20th-century analytic philosophy. As indicated above, the other main wing is the tradition that has its roots in Frege's and Russell's logic and extends through the work of Rudolf Carnap (1891–1970), Alfred Tarski (1901–1983), Kurt Gödel (1906–1978), and the other logical positivists and mathematical logicians, to W. V. O. Quine (1908–2000), Donald Davidson (1917–2003), Saul Kripke (1940–), and others. In this branch of analytic philosophy, there is greater concern with technical matters of logic and with its further development and use in understanding basic semantic concepts such as truth, logical consequence, and necessity. Possible world semantics, originating in Kripke's early seminal papers on modal logic, is perhaps the best example of recent work in this tradition, although Davidson's development of Tarski's work has been crucial in the huge interest that there now is in theories of meaning. On the more informal side, Quine's critique of Carnap's analytic/synthetic distinction has been both influential and controversial (Quine, 1951). Quine made this critique to show the essential continuity of philosophy and science, with a consequent rejection of the view that there is something distinctive about conceptual analysis. But recent years have seen various defenses – albeit in new contexts – of conceptual analysis, most notably by Frank Jackson (1998).

Analytic Philosophy Today

The two wings of analytic philosophy identified here represent, perhaps, the most important divide within analytic philosophy, a divide that was debated in Richard Rorty's classic collection of papers, *The linguistic turn* (1967). The tension between those who see philosophical progress as lying in ever more sophisticated logical, metaphysical, and scientific theories and those who see the task of philosophy as one of conceptual clarification rooted in ordinary linguistic practices has been a persistent theme throughout the history of analytic philosophy. If there is one insight that might be singled out as lying at the heart of analytic philosophy, then it is this: that our use of language is often 'systematically misleading,' to use Ryle's (1932) phrase. But responses to that insight have varied considerably. Analytic philosophy today is a broad-ranging and complex set of intertwining subtraditions whose unity is constituted lessby any distinctive set of doctrines than by their shared history. Understood like this, despite suggestions by some that we have now entered a 'postanalytic' age, analytic philosophy can be regarded as stronger and healthier today than it has ever been in the past.

Analytic/Synthetic, Necessary/Contingent, and *a Priori/a Posteriori*: Distinction

R Elugardo, University of Oklahoma, Norman, USA

© 2006 Elsevier Ltd. All rights reserved.

Three distinctions – necessary/contingent, *a priori/a posteriori*, and analytic/synthetic – mark three different contrasts. The *a priori/a posteriori* distinction marks an epistemological contrast between two different ways of knowing some proposition or two different ways of being justified in believing a proposition. The necessary/contingent distinction marks a modal contrast between different propositions. The analytic/synthetic distinction marks a semantic contrast between different sentences. Until the work of Immanuel Kant, the prevailing view was that either every truth is strictly necessary, *a priori*, and analytic, or it is contingent, *a posteriori*, and synthetic. Suffice it to say that things have gotten a lot more complicated since Kant. Many philosophers are even dubious about the reality of some or all of these distinctions. In this article, I will sketch the main ideas behind each dichotomy and note some points of controversy.

Necessary/Contingent Distinction

Necessity and contingency are said to be metaphysical properties of propositions, primarily *de dicto* modality. (For some general sources on the metaphysics of modality, see: Driver, 2002; Gendler

Analytic/Synthetic, Necessary/Contingent, and *a Priori/a Posteriori*: Distinction

R Elugardo, University of Oklahoma, Norman, USA

© 2006 Elsevier Ltd. All rights reserved.

Three distinctions – necessary/contingent, *a priori/a posteriori*, and analytic/synthetic – mark three different contrasts. The *a priori/a posteriori* distinction marks an epistemological contrast between two different ways of knowing some proposition or two different ways of being justified in believing a proposition. The necessary/contingent distinction marks a modal contrast between different propositions. The analytic/synthetic distinction marks a semantic contrast between different sentences. Until the work of Immanuel Kant, the prevailing view was that either every truth is strictly necessary, *a priori*, and analytic, or it is contingent, *a posteriori*, and synthetic. Suffice it to say that things have gotten a lot more complicated since Kant. Many philosophers are even dubious about the reality of some or all of these distinctions. In this article, I will sketch the main ideas behind each dichotomy and note some points of controversy.

Necessary/Contingent Distinction

Necessity and contingency are said to be metaphysical properties of propositions, primarily *de dicto* modality. (For some general sources on the metaphysics of modality, see: Driver, 2002; Gendler

and Hawthorne, 2002; Linsky, 1977; Loux, 1979; Lycan, 1994; Melia, 2003.) A proposition P is necessarily true just in case P is true and would have been true no matter how things might have been – the world could not have been such as to render P false. P is necessarily false just in case P is false, and it would have been false no matter how things might have been – the world could not have been such as to render P true. (Notice that we defined *de dicto* necessity in terms of possibility and negation: necessarily P $=_{\text{defn}}$ ¬Possibly ¬P. We could just as well have defined *de dicto* possibility in terms of necessity and negation: possibly P $=_{\text{defn}}$ ¬Necessarily ¬P. There is a sense, then, in which one cannot give a definition of an alethic modality that goes beyond this circle.) A proposition P is contingently true/false just in case P is true/false but could have been false/true (if the world had been otherwise in certain respects). The necessary/contingent distinction is therefore jointly exhaustive and mutually exclusive of every proposition that has a truth-value.

Sentences (1a), (2a), (3a), and (4a) are examples of necessary truths:

(1a) $12 \times 2 = 24$.

(2a) Gold has atomic number 79.

(3a) Biological parents have at least one offspring.

(4a) All dogs are dogs.

Sentences (1b), (2b), (3b), and (4b) are necessary falsehoods:

(1b) $12 \times 2 = 25$.

(2b) Gold is not an element.

(3b) Some biological parents have no offspring.

(4b) Some dogs have fleas and no dog has any fleas.

Sentences (1c) and (2c) are contingent propositions:

(1c) Al Gore won the 2000 U.S. Presidential Election.

(2c) Water freezes below 32°F.

Although (1c) is false, it might have been true if only Gore had received more electoral votes than Bush from the state of Florida. By the same token, although (2c) is true, it might have been false. After all, the laws of physics and chemistry might not have held to the extent and degree that they do. If they hadn't, then it would not have been true that water freezes below 32 °F.

Not all necessary truths are of the same kind. For example, (2a) is a metaphysically necessary truth – it is metaphysically impossible that the atomic number of gold not be 79, i.e., nothing could possibly be gold unless it is an element whose atomic number is 79. Mathematical Platonists who regard numbers as mind-independent abstract objects view (1a) as being a metaphysically necessary truth. According to them, the number 24 could not possibly have been distinct from the number that is the product of 12 and 2, which is the number 24 itself, since nothing can possibly be diverse from itself. The basic idea is the same in both cases: certain statements about a mind-independent reality must be true because of certain metaphysical facts about that reality (as opposed to facts about how we think about it).

Sentence (3a) is said to be a conceptually necessary truth because the concept of being a biological parent includes, as one of its conceptual components, the concept of having a biological offspring. Sentence (3a) is not so much a truth about the world as it is a truth about the concepts we use in thinking about the world. On this view, conceptual necessity is determined solely by the inferential relations that are (allegedly) constitutive of the contents of concepts that are so related. If lexical concepts have internal definitional structure, then (3a) is true by definition and thus, for that reason alone (according to philosophers like A. J. Ayer), it is a necessary truth (see Ayer, 1946).

Sentence (4a) is an example of a logically necessary truth, since it is an instance of the tautological schema 'All Fs are Fs,' which admits of no possible counterexample. A counterexample to that schema would be a case involving some F that was simultaneously non-F, which is a flat-out contradiction and thus impossible. Because they are not made true by any metaphysical facts about the world, logically necessary truths aren't metaphysically necessary. Nor are they conceptually necessary, since they are not made true by any facts about the (nonlogical) concepts we use to think about the world. They are necessarily true simply by virtue of their logical form.

The *a Priori/a Posteriori* Distinction

The *a priori/a posteriori* distinction is an epistemological distinction: it characterizes the way a proposition is known or the way a person is justified in believing the proposition. (For more discussion on the *a priori/a posteriori* distinction, see: Boghossian and Peacocke, 2000; Bonjour, 1998; Casullo, 1999; Casullo, 2003.) As Kant presents it, *a priori* knowledge is knowledge that one has independently of all possible sense experience. What makes *a priori* knowledge *a priori* for Kant is its universality – it is knowledge of that which constitutes the formal constraints on *all* possible human experiences – and its necessity. For Kant, knowing that every event has

a cause is a case of *a priori* knowledge. By contrast, *a posteriori* knowledge is only possible through experience or introspection. For example, knowing that several hurricanes caused massive destruction throughout Florida in 2004 is a case of *a posteriori* knowledge; you couldn't know that proposition is true merely on the basis of rational reflection.

The evidential source of *a priori* knowledge is neither sensory perception, nor introspection, nor memory. For you to be justified *a priori* in holding a belief, it is enough that you rightly recognize the truth of your belief given only your conceptual grasp or understanding of the content of your belief. Your reason for belief has to emerge from rational reflection or from rational insight, assuming that you have a nonempirical faculty of intellection. *A priori* knowledge may require experience to provide the relevant concepts, but, given possession of the concepts, no further role for experience is required for having *a priori* knowledge, except insofar as it can play a preservative role in the transmission of *a priori* justification from one source to another, e.g., testimony.

If *a priori* knowledge is genuine, then propositions (5a), (6a), and (7a) are examples of *a priori* knowable truths:

(5a) The relation *x is taller than y* is asymmetrical and transitive.

(6a) Whatever is colored is extended.

(7a) Whatever is red all over is not blue.

In each case, you can know the truth of the proposition simply by grasping its content, reflecting on what would have to be the case for it to be true, and then coming to recognize that the proposition must be true given your understanding of its content. Empirical observation plays no justificatory role in one's being warranted in believing (5a), (6a), and (7a). Knowledge of propositions (1a), (3a), and (4a) above would also be *a priori*.

By contrast, knowledge of (5b), (6b), and (7b) is *a posteriori*, since one's intellectual grasp of their contents is insufficient to secure epistemic warrant; moreover, one needs empirical evidence in order to be justified in believing them:

(5b) Yao Ming (the famous Chinese NBA basketball player) is taller than Danny DeVito (the popular film actor and comedian).

(6b) That car has a black exterior and is compact.

(7c) Some of these cardboard shapes are painted red on the facing side.

Whether there really is *a priori* knowledge is a matter of great debate. Rationalists and Kantians contend that some knowledge is *a priori*, while Quineans, who adopt a naturalistic approach to epistemology, deny the reality of *a priori* knowledge. (For more on this topic, see: Boghossian and Peacocke, 2000; Bonjour, 1998; Casullo, 1999, 2003; Devitt, 1994; Moser, 1987.)

It is quite natural to think that all and only *a priori* knowable propositions are necessary truths. For example, A. J. Ayer presents the following argument for their identification in Ayer (1946). First, if a proposition is *a priori*, then it can be known to be true independently of any experience of the world. But if that's true, then the truth of an *a priori* proposition must not depend on any contingent features of the world; otherwise, one would have to determine whether those features actually obtained in order to know whether the proposition is true – and then it would be an *a posteriori* proposition. Thus, an *a priori* proposition must be true no matter how things might have turned out in the world, which is the mark of a necessary truth. Second, if a proposition is a necessary truth, then it is true independently of the way things are. In which case, sense experience cannot play any role in explaining how we can know that proposition since experience can only furnish information about how things actually are, and not about how things must be. So, a proposition is *a priori* if it is a necessary truth.

Although Ayer's arguments contain some questionable steps, his arguments are not wildly implausible. More importantly, they set up a major challenge to his empiricism. If, as he and Carnap (1956) claim, mathematical and logical truths are necessary, and hence *a priori*, then we can have nonempirical knowledge; but then we can have some nonexperiential access to certain substantive facts about the world. That conflicts with Ayer's and Carnap's view that sentences, including sentences that express the contents of our knowledge, can have meaning only by being verifiable in principle. Ayer and Carnap thought they could solve this problem by explaining an *a priori* and necessary truth in terms of a linguistic notion of analyticity, namely, a sentence that is true by definition (Ayer) or by linguistic convention (Carnap). The idea is that any sentence that is true by definition must be necessary because, contrary to appearance, it contains no information about the world anyway. At the same time, it must also be *a priori*, because to know the proposition that such a sentence expresses is simply to know the definitional meanings of the terms that make up the sentence, which is enough to know that the sentence is true; experience plays no additional justificatory role. As we shall see later, Quine argued that the Ayer-Carnap gambit ultimately fails. Let us turn,

though, to Saul Kripke's view on the connection between the necessary/contingent and the *a priori/a posteriori*.

Kripke on the Necessary *a Posteriori* and the Contingent *a Priori*

As noted in the last section, the prevailing view among philosophers until the 1970s was that all and only necessary truths are *a priori* and that all and only contingent truths are *a posteriori*. Most philosophers have now abandoned the view, thanks largely to Kripke (1972/1980). According to Kripke, metaphysical necessity is not a criterion for the *a priori* since they track entirely different kinds of properties (alethic modal properties and epistemic properties, respectively) of different kinds of things (propositions/sentences and ways of knowing a proposition, respectively). So it should come as no surprise that both can sometimes come apart.

Kripke's example of a sentence that expresses a necessary *a posteriori* truth is 'Water is H_2O.' According to him, the terms 'water' and 'H_2O' are each **rigid designators**: they refer to their bearers in every possible world. Thus, 'water' rigidly designates water, and 'H_2O' designates rigidly the chemical substance that is composed of H_2O molecules. Given that water is chemically composed of H_2O molecules, the two terms co-refer in every possible world. There is no possible world in which something is identical to H_2O but isn't water, so 'Water is H_2O' is true in every metaphysically possible world. It therefore expresses a metaphysically necessary truth.

According to Kripke, that water is H_2O is *a posteriori* knowable. First, it is *a priori* and necessarily true that a substance's chemical composition is essential to it. Hence, anything that has the same chemical nature as water must of necessity be identical to water. However, we can't deduce anything about the actual particular nature of water from the concept of its being a chemical substance or from the concept of its having an empirical nature that is essential to water. We have to do some empirical investigation instead. Only when our best scientific theories have confirmed that the chemical nature of water is H_2O can we then be justified in believing that water is H_2O. Therefore, our knowledge that water is H_2O, which is a necessary truth, is *a posteriori*. In general, all true scientific identities are, for Kripke, necessary *a posteriori* truths. If Kripke was correct, then a proposition's being a metaphysically necessary truth doesn't entail that it is an *a priori* truth. (Some of Kripke's followers deny that necessarily true scientific identities are *a posteriori* knowable; see Salmon, 1993.)

Kripke also holds that some contingent propositions are *a priori*. He gives the example of a speaker who introduces the measurement term 'one meter' to pick out the actual length of a certain stick kept in the science museum in Paris at time t (call the stick 'Stick S'). The speaker stipulates, "Let 'one meter' designate the length of Stick S." In Kripke's example, the speaker uses 'the length of Stick S at t' to designate the actual length that S has at time t, (where t is the time of the speaker's utterance of her stipulation). The description used determines the reference of 'one meter' but not its meaning. Although 'one meter' rigidly designates a certain length in all possible worlds, which in the actual world happens to be the length of Stick S at t, 'the length of S at t' does not designate anything rigidly. For there are possible worlds in which, when heat is applied to Stick S at t, S is not one meter long at t. Hence, the stipulative definition, properly interpreted, does not say that 'one meter' is to be synonymous with 'the length of S at t.' Rather, says Kripke, the speaker fixes the reference of 'one meter' by stipulating that 'one meter' is to be a rigid designator of the length that is the actual length of Stick S at t. Imagine now that the speaker goes on to assert, 'Stick S is one meter long.' According to Kripke, the sentence 'Stick S is one meter long' is true but not necessarily true, since S could have had a different length at t under appropriate stresses and strains, heatings or coolings. Consequently, the proposition expressed is contingent rather than necessary.

Kripke next argued that, since the actual length of Stick S was used to fix the reference of 'one meter,' the speaker knows automatically and without empirical evidence that S is one meter long. The speaker's very act of fixing the term's reference constitutes her non-empirical justification for her knowledge of said proposition; she does not have to appeal to any experience in order to know that the proposition she expressed is true. This is something, then, that the speaker who introduced 'one meter' in that way knows *a priori*. Thus, on Kripke's view, the speaker's utterance of 'Stick S is one meter long' expresses a contingent *a priori* truth. If Kripke is right, then a proposition's being a contingent truth doesn't entail that it is an *a posteriori* truth. (Not everyone agrees that Kripke's example is an example of a contingent *a priori* truth; see: Casullo, 1999; Moser, 1987; Soames, 2003.)

The Analytic/Synthetic Distinction

Immanuel Kant, who first coined the analytic/synthetic distinction in Kant (1781/1998), defined an analytic judgment as one whose predicate-concept is

contained in its subject-concept. Analytic judgments are 'explicative' in the sense that they add nothing new through the predicate to the subject, e.g., 'all bodies are extended.' A synthetic judgment is one whose predicate-concept is not contained in its subject-concept. Synthetic judgments are 'ampliative' in the sense that they add information to the subject concept that is new and that no analysis could possibly extract from it, e.g., 'all bodies are heavy.'

Although Kant held that all analytic truths are *a priori* and necessary, he didn't think that all *a priori* truths are analytic in his sense, e.g., truths of arithmetic. For instance, according to Kant, in judging that 12 is the sum of 7 and 5, one does not think of 12 when one thinks of the sum of 7 and 5. To affirm that 12 is the number that 7 and 5 sum to, one must also imagine certain changes in time, namely, the successive addition of units, which (for Kant) was an intuition of time. Consequently, the judgment that 12 is the sum of 7 and 5 is ampliative and is thus synthetic. It is also *a priori*, since the judged proposition is known independently of sense experience.

As many commentators have pointed out, Kant's characterization of the analytic/synthetic distinction excluded judgments that appear to be analytic even though they are not of the subject-predicate form, e.g., 'If Mary *persuaded* Susan to attend college, then Susan *intends* to attend to college.' A more inclusive account was therefore needed. (For a discussion of the history of the analytic/synthetic distinction, see: Coffa, 1991; Pap, 1958.)

Metaphysical Analyticity

Since Kant, philosophers have viewed the analytic/synthetic distinction as a semantic distinction between sentences rather than as a distinction between judgments of the subject-predicate form. The standard definition of analyticity is this: *A sentence is analytic if and only if it is true solely by virtue of the meanings (in other words, definitions) of its constituent terms*. Any true sentence that is not analytic is *synthetic*. For example, sentence (8) below is analytic because its truth-value is supposedly fixed entirely by its meaning and structure. By contrast, sentence (9) is synthetic because its truth-value is not fixed by its meaning and form alone; it also depends on how things are in the world it describes.

(8) All vixens are female foxes.

(9) All vixens are nocturnal predators.

Following Boghossian (1997), I will call the standard definition of analyticity 'metaphysical analyticity', since it is a metaphysical thesis about what constitutes a sentence's having the truth-value that it has. (There are some excellent out-of-print anthologies on the analytic/synthetic distinction: Sleigh, 1972; Sumner and Woods, 1969. Pap, 1958, is still one of the best sources on this topic even though it is dated.)

By our definition, an analytic sentence owes its truth-value entirely to its meaning and form irrespective of any worldly facts. Consequently, no such sentence can undergo a change in truth-value, from truth to falsehood, unless it also undergoes a prior meaning-change. If the sentence were to undergo a shift in meaning, then it would not be expressing the same true proposition as before, since any meaning-change would necessitate a change in the proposition it expresses. Therefore, no analytic sentence could ever be empirically refuted (assuming that there is no change in its meaning).

In his famous 1951 study, W. V. O. Quine argued that no sentence is immune to error (see also Quine, 1991). On the contrary, every sentence is open to possible refutation without any prior change of meaning. Thus, Quine denied that there are any analytic sentences in the metaphysical sense defined above. Let us, then, turn to his argument.

Quine's Belief-Revisability Argument

To set the stage for Quine's argument, I will briefly review the main points at the end of Quine (1951). In that article, Quine took aim against the traditional empiricist's 'dogma' that each meaningful sentence has its own experiential confirmation conditions apart from any background theory. For the empiricists, most notably Ayer (1946) and Carnap (1956), all substantial knowledge comes from experience. For them, confirming a sentence is just a matter of having the appropriate sensory experiences, ones that would confirm the sentence to some degree of probability. Having the appropriate sensations is enough, then, to verify a single sentence; you don't need to assume the truth of any other sentence in order to verify it.

Quine rejected that last claim, since he agreed with Pierre Duhem that our beliefs make contact with experience as a whole, not individually; see Duhem (1914/1954). Call that the Quine-Duhem Thesis. Verifying a single sentence presupposes, then, a massive background of beliefs and default assumptions, which brings us to Quine's Confirmation Holism: *the evidential status of any one belief is fixed by its evidential relations to other beliefs, and their evidential status is in turn fixed by their evidential relations to many other beliefs, and so on for all of one's beliefs*. Thus, no single experience or group of experiences could ever refute or confirm a sentence

independently of its evidential connections to many other sentences.

It follows from the Quine-Duhem Thesis and Quine's Confirmation Holism that revising any one belief will necessitate a wholesale revision of one's belief-system. Quine presented his famous "web of belief" metaphor in Quine (1951) to explain this idea more fully. The beliefs that form the center of the 'web' are the ones that are almost impossible to give up (classical truths of logic, mathematical truths). The ones at the extreme ends of the web are the ones that are very easy to give up (observational beliefs), and the ones in between are relatively easy/hard to give up (scientific theoretical beliefs). Still, any belief can be rationally given up or revised for the right price and, by the same token, any belief can be held tenaciously, come what may, but at a cost. What to revise will depend on how much it will cost to preserve the system with respect to its coherence, simplicity, predictive power, and elegance. Belief-change, then, is solely a function of practical utility: change those beliefs that will require the least amount of changes in the rest of your belief-system while maximizing coherence, simplicity, etc.

Quine's Belief-Revisability Argument against the reality of analytic truths consists of just three premises. First Premise: Quine's Confirmation Holism – there are sentences that you hold true and sentences that you hold false, but in each case the support of your belief is a complex matter of the holistic evidential relations your sentence bears to many other sentences. Second Premise: if Quine's Confirmation Holism is true, then no belief or sentence is completely immune to revision; every sentence can be rejected under pressure from empirical evidence plus a concern for overall coherence. (Putnam, 1983, is an interesting objection to this premise.) Third Premise: if there are any analytic sentences as traditionally conceived, then they must be unresponsive to the world's input, and so immune to revision. Therefore: there are no analytic sentences as traditionally conceived.

Frege-Analyticity

A different conception of analyticity can be found in Frege (1968) and is one that is also discussed in Quine (1951): *A sentence is analytic if and only if either (i) it is a logical truth, or (ii) it can be converted into a logical truth by substitution of* ***synonymous*** *expressions*, salva veritate, *and formally valid inferences*. Clause (i) mentions a logical truth, which, according to Quine, is any true sentence that remains true under every uniform semantic interpretation and reinterpretation of its component, nonlogical, descriptive terms. Consider, for example, sentence (10):

(10) Every brother is a brother.

The nominal 'brother' is the only nonlogical descriptive term occurring in (10); (10) is true and it remains true under every possible, uniform, (referential) interpretation of the two occurrences of 'brother.' It is therefore a logical truth and thus analytic by clause (i).

Consider now sentence (11):

(11) Every brother is a male sibling.

Although (11) is true, it is not a logical truth, since one could consistently reinterpret 'brother' and 'male sibling' differently by assigning different extensions to them, resulting in a reading under which (11) is false. Still, it can be transformed into a logical truth by replacing 'male sibling' in (11) with its synonym 'brother,' which then yields (10). Thus, (11) is analytic by clause (ii) of our definition even though it is not a logical truth.

Nothing in this account entails anything about what constitutes the truth-value of an analytically true statement. Nor does it entail any unrevisability claim. Thus, Quine's Belief-Revisability Argument does not apply to this form of analyticity, at least not in any obvious way. Again, following Boghossian (1997), I will call this general account of analyticity 'Frege-analyticity.'

Is there a connection between the *a priori* and Frege-analyticity? If *a priori* knowledge is genuine, then logical truths like (10) are *a priori* knowable. Having the appropriate sense experiences is necessary for acquiring the concept of dog, but beyond that no empirical evidence is needed to know that if something is a dog, then it is a dog. Grasping the conditions under which (10) is true suffices for knowing that it is true, regardless of whether there are dogs and regardless of whether one has observed any dog. (11) would also be *a priori* since mere rational reflection and understanding of what the two synonyms mean provides one with the sufficient warrant needed to be justified in believing (11), and hence in knowing (11) *a priori*. Generally speaking, if there are any *a priori* knowable truths at all, then all Frege-analytic truths are *a priori* knowable for the kinds of reasons just mentioned.

Not all *a priori* knowable truths are Frege-analytic, however. For example, we said earlier that (5a), (6a), and (7a) are *a priori* knowable:

(5a) The relation *x is taller than y* is asymmetrical and transitive.

(6a) Whatever is colored is extended.

(7a) Whatever is red all over is not blue.

None of them is a Frege-analytic truth since none is a logical truth, nor can any of them be transformed into

one by substitution of synonyms, *salva veritate*. If anything, (5a), (6a), and (7a) are examples of synthetic *a priori* truths, assuming that the distinction between Frege-analytic and Frege-synthetic truths is genuine, exhaustive, and mutually exclusive. This notion of analyticity won't be useful, then, to logical positivists who attempt to reductively explain all *a priori* truths in terms of analyticity.

There are Frege-analyticities if there are logical truths, which Quine admitted there are. That is important for two reasons. For one thing, as we saw, Quine thinks that any logical truth is revisable. If he is right, then some Frege-analytic truths are rationally revisable; in that case, his Quine's Belief-Revisability Argument won't apply to this kind of analytic truth. For another, Quine himself admits in Quine (1951) to having a clear idea of a logical truth whose meaning, but not its truth-value, is implicitly fixed by stipulative definition, even though he thinks that logical truths are open to possible rational revision. It would be inaccurate to say, then, that Quine thought there were no analytic truths in any sense whatsoever. However, he did think that were sense in which there are analytic truths, namely, logical truths, is philosophically uninteresting and trivial, and is certainly not robust enough to erect a substantive epistemology of the sort that rationalists envision.

Quine also denies that there are Frege-analyticities of the second variety: sentences that can be transformed into logical truths by substitution of synonyms by synonyms. These are the ones that overlap with the conceptually necessary truths that Ayer and Carnap claimed we can know *a priori*, and quite cheaply, without sacrificing empiricism's main tenets about meaning or empirical content. Quine was dubious of conceptually necessary truths of any sort, so we should present his general argument for the denial of Frege-analytic truths of the second kind. (I count the following, along with Frege, as defenders of Fregean-analyticity, with their own nuanced views about synonymy and belief-revision: Chomsky, 1988, 2000; Katz, 1967, 1972, 1990; Putnam, 1962, 1965. Gilbert Harman and William Lycan are opponents of Frege-analyticity for largely Quinean reasons; see Harman, 1967a, 1967b; Lycan, 1994.)

Quine's Objections to Frege-Analyticity of the Second Kind

For Quine, the crucial question is whether we can explain synonymy without presupposing, either directly or indirectly, any notion of analyticity, given that we are trying to explain analyticity. In his 1951 study, Quine considers five analyses of synonymy and argues that they fail on independent grounds or they violate his noncircularity constraint.

The first proposal he considers was that two expressions are synonymous if and only if they have the same meaning. The problem is that the notion of two expressions having identical meanings is just as obscure and in need of explanation as the notion of analyticity. An account of synonymy that doesn't appeal to such mysterious entities as meanings is preferable to one that posits them.

The second proposal is that two expressions are synonymous just in case they can be mutually interchanged in any simple, **extensional**, sentence without changing its truth-value. This account fails to give a sufficient condition for synonymy. The predicates 'is a (normal healthy) creature with a heart' and 'is a (normal healthy) creature with a kidney' are true of exactly the same things. So, one could replace the former with the latter in sentence (12), resulting in sentence (13), without a change in truth-value:

(12) Every creature with a heart is a creature with a kidney.

(13) Every creature with a heart is a creature with a heart.

However, the two predicates are not synonymous, since (13) is supposedly analytic and *a priori* but (12) is neither.

The third proposal is that two expressions are synonymous just in case they can be interchanged in any **intensional** sentence without changing its truth-value. As Quine points out, the restrictive interchangeability criterion fails his first constraint. Consider sentences (14) and (15):

(14) Necessarily, all and only brothers are brothers.

(15) Necessarily, all and only brothers are male siblings.

According to the criterion, if 'brother' is synonymous with 'male sibling,' then (15) has to be true since (14) is. However, we can't determine whether (15) is true unless we first know whether the sentence 'all and only brothers are male siblings' is analytic. After all, the only reason one would have for thinking that (15) is true is if one believed that its embedded sentence expressed a conceptual truth. But to say that it is a conceptual truth that all and only brothers are male siblings is tantamount to saying that it is an analytic truth, which violates Quine's noncircularity constraint.

The final criterion for synonymy that Quine considered is this: two expressions are synonymous if they are interdefinable. Appealing to definitions is unhelpful since, as Quine noted, there are different

kinds of definitions. For example, dictionary definitions are reports of prior synonymies, in which case the final criterion is circular, and thus trivial. Nor will it do to say, as Ayer and Carnap have, that a definition is simply a semantic rule or meaning postulate. By that understanding, two expressions are synonymous if and only if they are correlated with one another in virtue of some (non-empirical) semantic rule of the language. The label 'semantic rule' is arbitrary, implying only the appearance of a particular sentence (or a schema) under the heading 'Semantic Rules.' At best, a semantic rule of a language L can only specify which sentences (if any) of L have the honorific status of being analytic-in-L if there are any, but it won't help explain the absolute, nonrelativistic, sense of analyticity. Moreover, different sets of truths could have appeared under that heading without a change in the total set of truths in the language. Not only is the appeal to semantic rules and meaning postulates arbitrary and unmotivated, but also it cannot settle decisively the question of whether a sentence like 'everything that is green is extended' is true by definition, or whether it expresses an important empirical truth about the world. Presumably it is one or the other, and it cannot be both. Since there are many borderline cases of just this sort, the Fregean analytic/synthetic distinction is unprincipled. On the assumption that his 'divide-and-conquer' strategy is successful, Quine concluded (Quine, 1951) that the notion of Frege-analyticity is empty and thus can serve no useful theoretical explanatory purpose.

Grice and Strawson (1956) is a famous response to Quine's argument; cf. Putnam (1965, 1970). According to Grice and Strawson, the terms 'analytic' and 'synthetic' must mark a genuine distinction, since they have a determinate philosophical use. Generations of philosophy students have learned these terms, and many of them can instantly recognize the real differences between the standard examples. Moreover, those who are adept in applying the distinction will agree about new cases. No doubt there will be difficult cases, as in 'everything that is green is extended' or perhaps 'all cats are animals,' but it does not follow that the analytic/synthetic distinction is not genuine. (Chomsky, 2000, makes a similar point.) The fact that there are borderline cases doesn't show that there are no clear cases of the distinction. Suppose there is no genuine difference in semantic status between analytic and synthetic sentences. Then there couldn't be any clear cases of analytic and synthetic truths or any agreement on the application of these terms to new cases. And yet, as they point out, even Quine would admit that a logical truth (e.g., 'all dogs are dogs') is analytic and not synthetic in some intuitive sense. According to Grice and Strawson, Quine's adequacy constraints on any plausible account of analyticity or synonymy are too stringent, unreasonable, and arbitrary; they have the undesired effect of rendering any linguistic elucidation of a group of family-related concepts impossible. In their view, Quine has only shown that no satisfactory analysis of analyticity has yet been provided, and not that no such distinction could be made. (Grice and Strawson never said what analyticity amounts to; nor did they show that the analytic/synthetic distinction is exhaustive.)

Until the late 1990s, much of the "analytic/synthetic" literature since the 1950s focused on the question of whether Quine succeeded in undermining the distinction. The prevailing view since Quine (1951) is that Quine did indeed win the battle, and that he also won the war against logical positivists, who tried to salvage empiricism while granting that we have knowledge of certain *a priori* necessary truths; see Soames (2003). Since the 1990s, there has been a resurgence of rationalism, and thus a reaction against Quine's epistemology and his arguments against the tenability of any substantive analytic/synthetic distinction. The writings of Bealer, Boghossian, Bonjour, Katz, and Peacocke helped fuel this resurgence. I will conclude this article with Boghossian's main contribution to the analytic/synthetic debate.

Epistemological Analyticity

Paul Boghossians defends an epistemic notion of analyticity in the spirit, if not the letter, of Ayer (1946) (see Boghossian, 1996, 1997): *A sentence is analytic if and only if grasping what the sentence means suffices in one's being justified in believing in the truth of the proposition that the sentence expresses.* Ayer and Boghossian differ in their emphasis: Ayer explained the *a priori* in terms of a linguistic notion of analyticity, whereas Boghossian explains analyticity in terms of *a priori* justification. They also differ as to whether implicit definitions can literally determine the truth-value of a sentence: Ayer thought they can, but Boghossian does not. Boghossian's motivation for defending an epistemic account of analyticity was that he thought it had the best chance of explaining our having nonempirical knowledge of logical truths and logically valid inferences – assuming that the meaning of a logical constant is fixed by its conceptual role in formally valid patterns of logical inference, which may be something we can grasp by means of an implicit definition. (Boghossian thinks that, regardless of how one conceives of analyticity, one has no choice but to take analyticity as a genuine substantive property of certain sentences if one is a realist about meaning, which he is. For space

constraints, I will sidestep the meaning/realism issue in this article.)

Suppose that you utter (16) and you go on to assert (17) (the example is from Lycan, 1994, although the main idea goes back to Ayer and Kripke):

(16) By 'veline' I shall henceforth mean 'a vegetarian cat.'

(17) All veline cats are vegetarians.

Then, just by virtue of grasping the content of your utterance of (16), which fixes the meaning of 'veline' in your idiolect, you are justified in believing that the proposition you expressed by your utterance of (17) is true. Hence, (17) (as tokened by you) is epistemically analytic.

Notice that, on Boghossian's epistemic account of analyticity, one can explain why such statements as (5a), (6a), (7a), (10), and (11), are *a priori*:

(5a) The relation *x is taller than y* is asymmetrical and transitive.

(6a) Whatever is colored is extended.

(7a) Whatever is red all over is not blue.

(10) Every brother is a brother.

(11) Every brother is a male sibling.

In each case, we have a *prima facie a priori* warrant to believe the proposition expressed because we have, in each case, a sufficient grasp of an implicit definition of an expression's meaning – either tacitly in our behavioral use of the expression or by way of an explicit stipulative definition. According to Boghossian, and apparently Kripke, our grasp of an implicit definition, which creates a semantic fact, constitutes our justification for believing the proposition expressed by the sentence containing the expression.

As Boghossian notes, Quine had no qualms about stipulative definitions if they are just arbitrary rules that implicitly define the meaning of a symbol. Thus, Quine could not object to the use of stipulative definitions *tout court*. He would object to the suggestion that stipulative definitions can literally create – by linguistic fiat or by linguistic convention – factual **truths** and **valid** inferences that are **unrevisable in principle**; see Quine (1935, 1960, 1966). However, Boghossian never claimed that implicit definitions determine the truth-value of a sentence or that they determine the validity of a logical inference. Rather, he claimed that implicit definitions literally create meaning-constituting facts the cognitive grasp of which sufficiently warrants semantic belief. If anything, they determine the proposition expressed but not the proposition's truth-value. Thus, as far as Boghossian is concerned, Quine's arguments (1935 and 1966) at best show that, contra Ayer and Carnap, implicit definitions cannot literally create truths by convention or by speaker intention. They don't show, argued Boghossian, that implicit definitions cannot have a meaning-constituting-factual role or an epistemic role in an explanation of *a priori* knowledge of logic.

Gilbert Harman, who defends the Quinean view, rejected Boghossian's epistemic account of analyticity and the role of implicit definitions in an explanation of *a priori* knowledge; see Harman (1996). According to Harman, grasping the contents of one's stipulative linguistic intentions can never warrant semantic belief. The reason is that meaning stipulations are just working assumptions that can easily be given up and, as such, they provide no evidence for anything. They can no more create epistemic warrant for semantic claims than they can create truth-values from scratch. See also Lycan (1994) for objections to Boghossian's view.

Readers can be assured that this debate will continue. We can look forward to more interesting discussions on the three distinctions discussed in this article.

Anaphora and Coreference Resolution, Statistical

M Strube, EML Research gGmbH, Heidelberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Anaphora (*see* **Discourse Anaphora; Anaphora, Cataphora, Exophora, Logophoricity**) are an important linguistic device for the speaker or writer to signal the cohesion or local coherence (*see* **Cohesion and Coherence: Linguistic Approaches**) of a discourse. Anaphoric expressions comprise mainly personal and possessive pronouns (*see* **Pronouns**), demonstratives (*see* **Demonstratives**), proper names (*see* **Proper Names: Semantic Aspects**), and definite noun phrases (*see* **Descriptions, Definite and Indefinite: Philosophical Aspects**) when they are used to refer to something previously mentioned in the discourse. The linguistic expression realizing the previous mention is called the antecedent. In order to construct a coherent representation of the discourse, hearers or readers have to interpret or resolve anaphoric expressions. This task is difficult, because most anaphoric expressions are referentially ambiguous (i.e., they can potentially be used to refer to more than one antecedent). Their unambiguous resolution requires a considerable amount of linguistic and world knowledge.

From a linguistic point of view, anaphora resolution is defined as the task of finding the antecedent for an anaphoric expression. In the area of Natural Language Processing (*see* **Natural Language Processing: Overview**) the task early on was considered as identifying the entity a referring expression is used to refer to, the discourse entity. If multiple referring expressions are used to refer to the same entity, they are said to corefer (*see* **Coreference: Identity and Similarity**). Based on those theoretical assumptions, the task of anaphora resolution has been redefined as coreference resolution (i.e., to assign a referring expression the discourse entity it is used to (co)refer to). The discourse entity then may be viewed as a representation of the set of referring expressions that are used to refer to it, or as a representation of a coreference chain.

Definition of the Task

For applications like information extraction (*see* **Information Extraction, Automatic**) or automatic summarization (*see* **Summarization of Text, Automatic**), determining the antecedent of an anaphoric expression is not relevant. Hence, coreference resolution is the task most statistical approaches attempt to solve. In order to express coreference resolution as a machine learning task (*see* **Language Processing: Statistical Methods**), most often it is transformed into a binary classification task. During data generation, pairs of potential anaphors and potential antecedents are created as data instances. In the abstract text representation in Figure 1, three referring expressions that are used to refer to the same discourse entity are marked by dashes. Nine referring expressions used to refer to different discourse entities are marked by solid lines. If we consider only the last referring expression as a potential anaphor, this results in 11 instances (i.e., pairs of a potential anaphors and potential antecedents). This data generation strategy creates a very large number of instances.

The classification task then can be formulated as follows: given a pair of potential anaphor and potential antecedent, classify as positive if anaphor and antecedent are in fact coreferent (i.e., both referring expressions are used to refer to the same discourse entity). Classify as negative otherwise. This is shown in Figure 2, where a dashed arrow indicates a positive classification, solid arrows negative ones. This results in two positive instances and nine negative ones. This data generation strategy, which was used successfully by Aone and Bennett (1995), may lead to a problem with the distance feature (i.e., the feature which captures the distance in words or sentences between anaphor and antecedent) in the case of long coreference chains.

In order to avoid that problem, the learning task can be formulated as follows: given a pair of potential anaphor and potential antecedent, classify as positive if the antecedent is in fact the closest antecedent, and as negative otherwise (i.e., label transitive positives as negative as shown in Figure 3). For positive instances, the distance feature should reflect the intuition that anaphors and their antecedents are rather close. However, this data-generation strategy leads to a highly skewed distribution of positive and negative instances. In Figure 3 there are ten negative instances and only one positive instance. Applied to real data, this strategy may yield more than 99% negative instances.

A strategy for reducing the large number of negative instances can be formulated as follows: given a

Figure 1 Abstract text representation.

pair of potential anaphor and potential antecedent, classify as positive if the antecedent is in fact the closest antecedent. Classify as negative only if the potential (wrong) antecedent is closer than the closest (correct) antecedent. Exclude all instances where the potential antecedent is farther away than the closest (correct) antecedent (i.e., exclude transitive positives and distant negatives; see Figure 4). However, this strategy is rather unintuitive. Intuitively, anaphor and antecedent should be rather close. Following this strategy, however, the distance between anaphor and antecedent in positive instances is always the maximum distance. Consequently, in Soon *et al.* (2001) the distance feature proved to be not important for solving the task.

Data

The most important prerequisite for statistical approaches is annotated data (*see* **Treebanks and Tagsets**). There exist several corpora annotated with information about coreference, e.g., the MUC-6 and MUC-7 corpora (available through the Linguistic Data Consortium (LDC)) (see 'Relevant Websites'). However, those corpora are rather small and idiosyncratic. A subset of the Penn TreeBank (*see* **Treebanks and Tagsets**) has been extended with information on pronouns and their antecedents by Ge *et al.* (1998) (available from them on request). The ACE corpus (Automatic Content Extraction) is available through the LDC. This corpus is substantially bigger than the MUC corpora, but only anaphoric relations relevant to the ACE program are marked.

If a statistical approach is to be applied to a new genre, domain, or language, data have to be annotated with information about anaphoric relations. This can be done manually or semiautomatically, using annotation tools (e.g., the annotation tool MMAX) (see 'Relevant Websites').

Evaluation

The evaluation (*see* **Natural Language Processing: System Evaluation** of the anaphora resolution task is straightforward. In the key (i.e., the data representing the solution for the task), each anaphor has exactly one antecedent. The response (i.e., the output of the anaphora resolution system) also contains exactly one antecedent for an anaphor. The performance of a system then can be measured in terms of the success rate and in terms of precision, recall, and F-measure (see Table 1 for a list of those terms and their abbreviations).

The success rate just compares the number of correctly resolved anaphors with the number of all anaphors in the document or corpus (Mitkov, 2002):

$$S = \frac{Nc}{Na}$$

An evaluation that reports precision, recall, and F-measure may prove more realistic, since a high recall, low precision system may still achieve a high success rate, though it may be not desirable for most applications.

$$P = \frac{Nc}{Nh}$$

$$R = \frac{Nc}{Na}$$

$$F = \frac{2PR}{(P+R)}$$

Problems with those measures arise because researchers often do not report exactly which types of anaphoric expressions are relevant for the evaluation, which types are filtered out manually, and which types their systems attempt to resolve. Therefore, the

Figure 2 Positive, if anaphor and antecedent are coreferent.

Figure 3 Exclude transitive positives.

Figure 4 Exclude transitive positives and distant negatives.

reported results are often not comparable (Byron, 2001).

Though there exists an established evaluation metric for the coreference resolution task introduced for MUC-6 by Vilain *et al.* (1995), this topic is still controversial.

Vilain *et al.*'s (1995) evaluation metric partitions the set of referring expressions into sets of coreferring expressions by computing the minimal number of links needed to create those sets. Both key and response consist of those sets. The difference between key and response is given by computing the minimal number of links to be deleted or created in order to transform the response into the key. Finally, precision, recall, and F-measure are reported on the basis of those numbers. This metric abstracts from the task of finding 'the' antecedent of an anaphoric expression. It reports a result which is very close to the task of coreference resolution as needed in real-world applications.

Notes on the Development of the Field

Research in the area of Natural Language Processing about anaphora resolution started out by modeling linguistic knowledge algorithmically (*see* **Anaphora Resolution: Centering Theory Approach**). Early work on pronoun resolution used the syntactic structure to define constraints and search procedures for determining pronouns' antecedents (Hobbs, 1978). Building upon refinements in linguistic theory, e.g. Binding Theory (*see* **Binding Theory**) and Discourse Representation Theory (*see* **Discourse Representation Theory**), pronoun and anaphora resolution algorithms were implemented within syntactic and semantic parsers.

Constraints or filters provided by those theories are only one part of the knowledge needed by an anaphora resolution algorithm. Constraints can only reduce the set of potential antecedents of anaphoric expressions. They cannot select the most likely antecedent. Hence, it is necessary to provide knowledge about preferences for certain candidates. Preferences are provided either by linguistically and psychologically motivated models, e.g., the centering model (*see* **Anaphora Resolution: Centering Theory Approach**), or by heuristics, e.g., Lappin and Leass, 1994. Most centering and heuristics-based algorithms rely on complete syntactic analysis. Since there are no parsers that provide a complete analysis robustly on unrestricted input (*see* **Parsing: Statistical Methods**), those algorithms were evaluated either only manually or automatically on a very restricted set of documents. However, in the mid-1990s the need to apply anaphora resolution algorithms to unrestricted input grew. This led to three important developments in the area of anaphora resolution. First, corpora were annotated with information about anaphoric relations, in particular due to the series of Message Understanding Conferences (MUC) (*see* **Text Retrieval Conference and Message Understanding Conference**). Second, heuristics were adapted such that their preprocessing demands decreased. Hence, anaphora resolution algorithms based on heuristics became more robust and could be applied to unrestricted input (e.g., Kennedy and Boguraev, 1996). Third, statistical and machine learning techniques were applied (Aone and Bennett, 1995; McCarthy and Lehnert, 1995).

Table 1 Terms used for evaluation

Na: number of all anaphors in a document or corpus
Nc: number of correctly resolved anaphors
Nh: number of resolutions attempted
S: success rate
P: precision
R: recall
F: equally weighted F-measure

State-of-the-Art Approaches

Decision Trees

Most work in statistical coreference resolution uses standard machine-learning algorithms (*see* **Language Processing: Statistical Methods**). The following description of a state-of-the-art technique in decision tree–based coreference resolution follows Soon *et al.* (2001).

Soon *et al.* used the corpora that were created for the coreference task of MUC-6 and MUC-7. The input to their system consists of raw data, i.e., data stripped from all kinds of linguistic information (annotation). Hence, a sequence of preprocessing components is needed to determine the extent of referring expressions and assign them values for the features shown in Table 2 (possible values of the features are given in parentheses). The preprocessing components

Table 2 Features used by Soon *et al.* (2001)

1. Distance	Distance between **ana** and **ante** in sentences (0, 1, 2, . . .)
2. i-Pronoun	Is **ante** a pronoun? (T, F)
3. j-Pronoun	Is **ana** a pronoun? (T, F)
4. String match	Are **ana** and **ante** identical (T, F)
5. Definite noun phrase	Is **ana** definite noun phrase? (T, F)
6. Demonstrative NP	Is **ana** a definite NP with demonstrative determiner? (T, F)
7. Number agreement	Do **ana** and **ante** agree with respect to number? (T, F)
8. Semantic class agreement.	Do **ana** and **ante** agree with respect to semantic classes which are arranged in a **isa**-hierarchy: **female, male, person, organization, location, date, time, money, percent, object**? (T, F)
9. Gender agreement	Do **ana** and **ante** agree with respect to gender? (T, F)
10. Both-proper-names	Are both **ana** and **ante** proper names? (T, F)
11. Alias	Are **ana** and **ante** similar (**substring match**, abbreviations, etc.)? (T, F)
12. Appositive	Is **ana** appositive of **ante**? (T, F)

used by Soon *et al.* are tokenization and sentence segmentation, morphological processing, part-of-speech tagging (*see* **Part-of-Speech Tagging**), noun phrase identification, named entity recognition (*see* **Named Entity Extraction**), nested noun phrase extraction, and semantic class determination.

Soon *et al.* then generated training data following the strategy already shown in Figure 4. Each instance in the training data is a feature vector describing the relation between a potential anaphor and a potential antecedent by means of the 12 features given in Table 2. Then, a standard decision-tree classifier is trained. The learned model is applied to testing data which are fed into the evaluation algorithm according to Vilain *et al.* (1995). The model can also be integrated into an NLP application.

Maximum Entropy

Lappin and Leass's (1994) heuristic algorithm for pronoun resolution proved to be popular among researchers implementing shallow approaches (e.g., Kennedy and Boguraev, 1996). However, Lappin and Leass's algorithm has the great disadvantage that the weights assigned to features have to be determined manually. An approach that allows the expression of the Lappin and Leass algorithm in statistical terms is the maximum entropy framework (Berger *et al.*, 1996), which learns the weights from the data automatically.

Applied to coreference resolution, the maximum entropy framework also requires generation of training and testing data in terms of binary classification (Morton, 2000). It relies on a set of binary features that define constraints on the statistical model that is learned. Given a set of those constraints, the model with the maximum entropy has to be identified (i.e., the model with the least amount of information beyond the constraints). The maximum entropy framework has been applied to coreference resolution by Kehler (1997) and Morton (2000), and to pronoun resolution by Kehler *et al.* (2004).

Statistical Modeling

Ge *et al.* (1998) described a statistical approach to pronoun resolution. In contrast to the work described above, they did not use preprocessing components. Instead they derived the following features from the Penn TreeBank enriched by them by anaphoric information: distance between pronoun and potential antecedent, gender, number, and animaticity of the potential antecedent, selectional restrictions of the head of the pronoun, and the number of times a discourse entity was referred to in a document. Given this information, Ge *et al.*'s statistical approach can be described as a function from pronouns to antecedents. Then they collected the relevant statistics from training examples and ran the program on test data. They computed probabilities for each potential antecedent and selected the one with the highest probability.

Unsupervised and Semisupervised Machine Learning

The approaches described above are supervised (i.e., they require data annotated with the target concept as input). Since this annotation is expensive in terms of cost and labor, unsupervised and semisupervised approaches are much sought after.

Cardie and Wagstaff (1999) presented an unsupervised approach to coreference resolution. They started out with the observation that all referring expressions in a coreference chain define an 'equivalence class.' Therefore, it would be natural to view

the coreference resolution task as clustering. Since all members of a coreference chain should be similar, their conceptual distance should be small. Given a method for measuring this distance, a clustering algorithm could group referring expressions together, such that coreferent ones end up in the same cluster.

Cardie and Wagstaff's system uses preprocessing components to assign values to features in vectors describing referring expressions (**not** pairs of potential anaphors and potential antecedents). Initially, each referring expression is assigned its own cluster. Then the algorithm works backward through the document, where each referring expression is compared with all preceding ones. If the distance between two referring expressions is less than the clustering radius *r*, they are considered for possible merging into one cluster. Cardie and Wagstaff evaluated their approach on the MUC-6 data. They reported a performance comparable to other systems presented at the MUC-6 conference. Their system outperforms the only machine-learning-based system presented there.

Unsupervised machine learning of natural language tasks is almost too difficult. Hence, semisupervised machine learning meta algorithms, e.g., Co-training (Blum and Mitchell, 1998), were applied. A Co-training classifier consists of two simple classifiers, which, initially, are trained separately using a small set of labeled training data.

Each of them is trained on a different subset of features (i.e., on different views of the data). The views have to be disjoint or even conditionally independent. The Co-training algorithm bootstraps by gradually extending the training data with self-labeled instances. It utilizes the two classifiers by letting them in turn label the best positive and best negative instances from the set of unlabeled training data. Instances labeled by one classifier are then added to the other's training data, and vice versa. After each turn, both classifiers are retrained on their augmented data sets. This process is repeated either for a given number of iterations or until all the unlabeled data have been labeled.

Co-training was applied to coreference resolution by Müller *et al.* (2002) and later by Ng and Cardie (2003). One result of this work was that the amount of training data needed to achieve reasonable performance on the coreference resolution task is rather small (Müller *et al.*, 2002).

Recent and Future Developments

Overcoming Problems with Binary Classification

Most state-of-the-art approaches to statistical coreference resolution redefine the task as binary classification. While this helps to apply standard classification-based machine learning algorithms, it has the following serious drawbacks:

1. Even for small documents, the binary classification approach generates very large training and testing data sets, which may prevent researchers from concluding experiments in a reasonable amount of time.
2. Each decision is independent from all other decisions. This may lead to contradictory results ($A = B$, $B = C$, $A \neq C$). This may also lead to unnecessary competition between compatible results ($A = B$, $B = C$, $A = C$; there is no need to resolve A twice).
3. Training instances do not have knowledge about the context of referring expressions. They do not have knowledge about other referring expressions used to refer to the same or a different discourse entity.

In order to avoid problem (1), a few modifications have been proposed. Though the testing data set must not be modified using the information about the target concept, the training data set can be minimized considerably (see **Figure 4** and a variation in Ng and Cardie, 2002).

In order to avoid the conflicts described in (2), different strategies can be applied. Most often, only one instance per anaphoric expression is allowed to be classified as positive. The standard approach is to select only the positive instance which contains the closest antecedent for an anaphoric expression. Ng and Cardie (2002) do not select the instance with the closest antecedent but the one with the highest confidence value returned by the classifier.

The most serious problem is given in (3). Yang *et al.* (2003, 2004) tried to address that problem. Yang *et al.* (2003) presented a competition learning approach (similar to the one by Connolly *et al.*, 1997), where each anaphoric expression is paired with two antecedents, a correct one and an incorrect one. The concept to be learned is which of the potential antecedents is the correct one. During classification, the algorithm is given initially one instance. It determines which of the potential antecedents is the better one. The loser is discarded. The winner is paired with some other candidate. This new instance is given to the classifier, which again determines the better one. That way the overall best antecedent for an anaphoric expression can be determined. The results reported by Yang *et al.* (2003) (on MUC-6 and MUC-7 data) indicate that this strategy outperforms state-of-the-art systems.

Yang *et al.* (2004) described another method of incorporating more contextual information into a pronoun resolution algorithm. In addition to

potential anaphor and potential antecedent, they extended the representation of each instance by a third referring expression, the closest antecedent of the potential antecedent (the set of features describing this referring expression is set to nil if there is no such expression). Yang *et al.* claimed that they are able to include knowledge similar to centering approaches (*see* **Anaphora Resolution: Centering Theory Approach**) and reported increased performance over baseline systems.

Luo *et al.* (2004) described a more general approach to make knowledge about the context accessible to a coreference resolution algorithm. They proposed the Bell tree as representation for the search space. The leaves in the Bell tree contain all possible outcomes (which is a very large number). The task of coreference resolution then is to find the best path from the root to the leaf nodes in the Bell tree. Nodes in the tree are made up of partial solutions. They contain sets of referring expressions representing coreference chains and singletons, which are not coreferent. Luo *et al.* (2004) used a maximum entropy framework (Berger *et al.*, 1996) to assign a referring expression to an existing set (coreference chain) or to create a singleton set. That way, they provided access to knowledge about other referring expressions in a coreference chain and to competing candidates. Luo *et al.* reported encouraging results on ACE and MUC data. Efficient search heuristics are necessary to implement this approach.

Integrating Linguistic and Extra-Linguistic Knowledge

Most of the work mentioned relies on a rather small set of linguistically simple features. There have been early attempts to include knowledge about predicate–argument structure by Dagan *et al.* (1995). Recently Kehler *et al.* (2004) evaluated the contribution of this knowledge to pronoun resolution. They found no significant improvement.

Some researchers also tried to include world or domain knowledge in statistical coreference resolution. Harabagiu *et al.* (2001) reported an improvement in performance by including knowledge from WordNet (*see* **WordNet(s)**).

Covering More Linguistic Phenomena

Most of the research on statistical coreference resolution is focused on English-language texts, either taken from MUC or from the Penn TreeBank. Aone and Bennett (1995) applied their approach to Japanese texts. Müller *et al.* (2002) worked with German (German, Standard) texts. Only when annotated data in other languages become accessible, can statistical methods be applied to more languages.

Existing approaches focus either on pronoun resolution in texts or on noun phrase coreference resolution in texts. Strube and Müller (2003) made the first attempt to apply machine learning methods to pronoun resolution in spoken dialogue. Nissim and Markert (2003) presented a statistical approach to metonymy (*see* **Metonymy**) resolution, and Modjeska *et al.* (2003) presented one to *other*-anaphora resolution. Due to sparse data, the latter two approaches first needed to identify relevant cases in large corpora. Then they applied standard machine learning techniques.

Anaphora Resolution: Centering Theory Approach

A K Joshi, R Prasad and E Miltsakaki, University of Pennsylvania, Philadelphia, PA, USA

Anaphora Resolution with Centers of Attention

Anaphora resolution in discourse – a coherent sequence of utterances – is the task or process of identifying the referents of expressions that we use to denote discourse entities, i.e., objects, individuals, properties, and relations that have been introduced and talked about in the prior discourse. The importance of modeling this process cannot be overstated. Computing the meaning of a discourse is commonly understood as partly the process of connecting the information in the upcoming utterance with the information contained in the prior discourse. Before we can do this, however, we need to assign an interpretation to all the elements of the utterance and then to the utterance as a whole. In many cases, the interpretation of some elements in the sentence can only be assigned relative to the prior discourse context – *anaphoric expressions* comprise one such class of elements.

In early approaches to anaphoric reference in AI and linguistics, the task of anaphora resolution was relegated to syntax, which provided filters, such as grammatical agreement constraints, and open-ended semantic inference that drew on, among other things, world knowledge and inference procedures to identify the appropriate referent. However, it was soon recognized that while syntactic constraints were very limited in constraining the search for anaphoric referents on the one hand, the mechanism of open-ended semantic inference, on the other hand, was too knowledge intensive and complex – requiring reasoning over the entire space of discourse at once – and therefore computationally unfeasible.

In 1977, a different view to anaphora resolution arose out of the work of Barbara Grosz (Grosz, 1977) that rests on a fundamental and singularly important assumption regarding the attentional status of discourse entities: at any given point of the discourse, the discourse participants' attention is centered on a set of entities, a proper subset of all the entities being talked about in the discourse. In addition, for a given utterance, the discourse participants' attention is centered on a singleton entity, and the rest of the utterance makes a predication about this entity. The notion of the center of attention specific to utterances is very similar to the notion of 'topic' in linguistics, where it is defined as what is 'talked about' in the utterance. The approach for anaphora resolution with this Centering view is that the search for the referents of anaphoric expressions should be restricted to the set of centered entities, the assumption being that in discourse, it is these entities that we are most likely to continue to talk about and refer to with the use of anaphoric expressions. Furthermore, a partial ordering is imposed on the elements of the set, so that some entities are more centered than others. Such a preference ordering on the possible candidate referents for anaphoric expressions significantly simplifies the 'nature' of inference that would be needed and at the same time minimizes the 'amount' of inference. Another significant proposal was that the set of centered entities can be partially determined by the linguistic structure of the utterance itself. The consequences for all these ideas were tremendous, because the view meant that it was possible to set aside, to a significant extent, the role of open-ended inferencing for anaphora resolution and look instead to more easily identifiable surface features of the utterance, such as the solution and explanation, for at least part of the problem.

While Grosz laid out the general framework for the Centering process, her work did not suggest the exact mechanisms whereby the centered entities could be identified. Candy Sidner (1979) extended Grosz's framework by precisely defining the notion of the utterance-based center linguistically and also provided a mechanism for using centers to identify referents of pronouns.

Sidner invoked several Centering structures – singleton sets called 'discourse focus' and 'actor focus,' and a set called the 'potential foci,' which can contain one or more elements. The 'discourse focus' is equivalent to the center of the utterance, i.e., the entity about which some predication is made by the utterance. The 'actor focus' is the discourse entity that is predicated as the agent of the event in the utterance. The 'discourse focus' is identified by using a set of rules that refer to the linguistic structure of the utterance as well as the state of the existing data structures when the utterance containing the pronoun is processed. A referent for a pronoun is identified primarily with the actor focus or the discourse focus, unless it is ruled out by some specified criteria, in which case an alternate candidate referent is considered from the set of 'potential foci,' which contains entities other than the two primary foci. A significant aspect of Sidner's work is that she did not rule out the role of inference in pronoun interpretation, but instead only constrained it in nature and amount. The nature of inference needed is different from earlier, open-ended inference systems in that it only involves

checking for contradictions once a candidate referent is chosen by using the structurally determined preference ordering: this allows for a much simpler knowledge base and reasoning procedures. The amount of inference needed is also reduced because of the preference ordering, so as soon as an entity is identified for which no contradictions arise, no other inferencing is needed.

Centering Theory: Modeling Local Coherence with Centers of Attention

Centering Theory (CT) arose from the work of Aravind Joshi and Steve Kuhn (Joshi and Kuhn, 1979), where the concepts of the 'center' and 'Centering' were first introduced as a way to specify an almost monadic calculus approach to discourse interpretation. Joshi and Kuhn showed that inferences of a certain class are more easily computed by using a monadic representation for utterances. However, they were also interested in computing the difficulty of deriving the necessary inferences.

While not explicitly stated by Joshi and Kuhn, the Centering process was assumed to be a local phenomenon operating over successive utterances. In the meantime, Grosz's work on global and local discourse processing had also been formalized by Grosz and Sidner (1986), and it was possible to place CT in its proper place in a complete theory of discourse processing. Grosz and Sidner provided a framework for discourse structure as a composite of three interacting constituents: a linguistic structure, an intentional structure, and an attentional state. The linguistic structure is determined by the intentional structure and comprises the utterances of the discourse grouped together hierarchically into discourse segments. The attentional state is an abstraction of the discourse participants' center of attention as the discourse unfolds. Each discourse segment is associated with a fixed attentional state relevant to the overall discourse – the global attentional state. A local attentional state is associated with each utterance within the segment. The local attentional state is inherently dynamic and can remain constant or can change from utterance to utterance within the segment.

Centering Theory (Grosz *et al.*, 1983, 1995) was proposed as a model of the local attentional state, i.e., of the dynamic attentional state within the discourse segment. Following up on the concerns of Joshi and Kuhn, it explicated more clearly and formally the particular linguistic and attentional state factors that contribute to the ease or difficulty of interpreting a discourse segment. The notion of inferential complexity or difficulty was recast as the term of 'coherence.' The first factor that contributes to coherence was given as a further explication of Joshi and Kuhn's 'change of center' rule and accounts for the difference in coherence between the discourse segments (1) and (2).

(1a) John went to his favorite music store to buy a piano.
(1b) He had frequented the store for many years.
(1c) He was excited that he could finally buy a piano.
(1d) He arrived just as the store was closing for the day.

(2a) John went to his favorite music store to buy a piano.
(2b) It was a store John had frequented for many years.
(2c) He was excited that he could finally buy a piano.
(2d) It was closing just as John arrived.

Discourse (1) is intuitively more coherent than discourse (2). This difference may be seen to arise from the number of changes in the center. Discourse (1) centers a single individual, 'John,' describing various actions he took and his reactions to them. In contrast, discourse (2) seems to flip back and forth between 'John' and 'the store.' These 'changes in aboutness' or 'changes of centers' makes discourse (2) less coherent than discourse (1).

The second observation that CT captures with discourses (1) and (2) establishes the correlation of center changes and the degree of coherence with the linguistic form of the utterances. Both discourses convey the same information but in different ways. They differ not in content or what is said but in expression or how it is said. The variation in 'changes of attentional state' that they exhibit arises from different choices of the way in which they express the same propositional content. The different linguistic choices further engender different inference demands on the hearer or reader, and these differences in inference load underlie certain differences in coherence between them.

In addition to the different linguistic choices pertaining to the realization of the propositional content of the utterance as a whole, CT also identifies different linguistic choices made for realizing particular elements within the propositional content of the utterance. These are choices in referring expression form. Pronouns and definite descriptions are not equivalent with respect to their effect on coherence. CT characterizes the perceived coherence of the use of pronouns and definite descriptions by relating different choices to the inferences they require the hearer or reader to make. In (3), the variations of a discourse illustrate this relationship.

(3a) Terry really goofs sometimes.
(3b) Yesterday was a beautiful day and he was excited about trying out his new sailboat.
(3c) He wanted Tony to join him on a sailing expedition.
(3d) He called him at 6 A.M.
(3e) He was sick and furious at being woken up so early.
(3e′) Tony was sick and furious at being woken up so early.
(3f) He told Terry to get lost and hung up.
(3g) Of course, he hadn't intended to upset Tony.
(3g′) Of course, Terry hadn't intended to upset Tony.
(3g″) Of course, Terry hadn't intended to upset him.

In discourse (3), it is the use of the pronoun in utterance (3e) that is in question. While we can tell that the pronoun *He* refers to 'Tony,' the use of the pronoun here is potentially confusing. CT claims that this is because until utterance (3d), 'Terry' has been the 'center of attention' and therefore the most likely referent of the pronoun. This claim rests on the assumption that hearers expect speakers to continue talking about the entity that is in the 'center of attention.' The confusion results because we tend to assign the reference of the pronoun to the center of attention as soon as we encounter it but have to backtrack (a phenomenon called 'garden path') when we process the rest of the sentence and find something that contradicts our assumption. In this particular example, we backtrack when we get to the work *sick* and, from the prior utterances in the discourse, reason that it must be 'Tony' and not 'Terry' who is sick. As the careful reader will have noticed, the assumed preferences for determining the referents of pronouns in CT are reminiscent of Sidner's model. We return to this comparison at the end of this section, where we discuss the relation between anaphora resolution and Centering theory.

The confusion arising from (3e) is removed if the pronoun is replaced with the full noun phrase 'Tony,' as shown in (3e′). The conjecture in CT, therefore, is that when the center of attention shifts to another entity, the form of referring expression used to denote the new centered entity has consequences for the processing load required for interpreting the utterance. A pronoun used to refer to the new centered entity increases the processing load, because it causes backtracking from the interpretation of the old centered entity and thus from the interpretation of the utterance itself. A full noun phrase, on the other hand, shifts the center of attention before the rest of the utterance is processed and therefore entails less processing.

The three variants (3g), (3g′), and (3g″) provide an illustration of yet another type of difference in coherence due to the form of referring expression. This arises when multiple entities are talked about from one utterance to the next. By the time (3f) is processed, the center has shifted from 'Terry' to 'Tony,' so that in (3g) we expect 'Tony' to be the center of attention. This expectation is borne out in (3g), since 'Tony' is indeed mentioned again. However, what makes this sentence very odd and hard to process is that 'Terry' is also mentioned in (3g), but while the centered 'Tony' is referred to with a full noun phrase, the noncentered 'Terry' is referred to with a pronoun. This increased processing is reduced when a full noun phrase is used for 'Terry' instead of the pronoun, as in (3g′) or (3g″), so that we are able to shift the center before processing the rest of the utterance, thus avoiding any backtracking. The type of coherence variation found in these utterances is due to the fact that both the centered entity in (3f) and another entity are mentioned again in (3g) and its variants, but in (3g) it is the noncentered entity from (3f) that is referred to with a pronoun.

CT provides a set of definitions, constraints, and rules to formalize the three-way relationship discussed above, i.e., the relationship between attentional state, the degree of coherence, and linguistic form (for the realization of full propositional content as well as for the realization of discourse entities). The CT definitions, constraints, and rules are given here.

Definitions:

D1. Each utterance U in a discourse segment is assigned a set of *forward-looking centers*, C_f (U), where *centers* are discourse entities realized in the utterance.
D2. Each utterance other than the segment-initial utterance is assigned a single *backward-looking center*, C_b (U).
D3. The *backward-looking center* of utterance U_{n+1} connects with one of the *forward-looking centers of* U_n.
D4. The elements of C_f (U_n) are partially ordered to reflect relative prominence or salience in U_n. In English, the C_f is ordered according to grammatical role.
D5. The more highly ranked an element of C_f (U_n), the more likely it is to be C_b (U_{n+1}).
D6. The most highly ranked element of C_f (U_n) is called the *preferred center*, C_p (U_n).
D7. A transition relation holds between each utterance pair U_n and U_{n+1} in a segment. There are four types of transitions, which describe center continuation, center retention, and two types of center shifting. The transitions are shown in Table 1.

Table 1 Centering transitions

	$C_b(U_{i+1}) = C_b(U_i)$ OR $C_b(U_i) = [?]$	$C_b(U_{i+1}) \neq C_b(U_i)$
$C_b(U_{i+1}) = C_p(U_{i+1})$	CONTINUE	SMOOTH-SHIFT
$C_b(U_{i+1}) \neq C_p(U_{i+1})$	RETAIN	ROUGH-SHIFT

Constraints:

C1. There is precisely one backward-looking center $C_b(U_n)$.

C2. $C_b(U_{n+1})$ is the highest-ranked element of Cf (U_n) that is realized in U_{n+1}.

Constraint C1 says that there is one central discourse entity that the utterance is about. Constraint C2 states that the ranking or ordering of the forward-looking centers in U_n determines which of them realized in U_{n+1} will become the backward-looking center of U_{n+1}.

Rules:

Rule 1. If some element of $C_f(U_n)$ is realized as a pronoun in U_{n+1} then so is $C_b(U_{n+1})$.

Rule 2. With respect to Table 1, sequences of the CONTINUE transition are preferred to sequences of the RETAIN transition, which are preferred to sequences of the SMOOTH-SHIFT transition, which are preferred to sequences of the ROUGH-SHIFT transition.

Rule 1 is often called the 'Pronoun Rule.' It is important to note that the inference load due to Rule 1 is not part of the inference load characterized by the transitions. Rule 1 is thus independent of the transitions. This independence of Rule 1 is an important consideration when one thinks of the relation between CT and anaphora resolution. The inference load due to Rule 1 can be regarded as a binary measure that simply states whether or not Rule 1 has been violated. With this rule, we can now explain the varying degrees of coherence for utterances (3g), (3g′), and (3g″) in discourse (3). The Centering analysis for this discourse is shown in Table 2. After 'Tony' is established as the center (the C_b) in (3e), this center continues in (3f), but with the reintroduction of 'Terry' as a potential center. In (3g), both 'Tony' and 'Terry' are mentioned, but since 'Tony' is higher ranked than 'Terry' in (3f), it is 'Tony' that is retained as the C_b in (3g). However, this utterance creates a Rule 1 violation, because the C_b, 'Tony,' is not realized with a pronoun, whereas 'Terry,' which is not the C_b, is. The only difference between (3g) and (3g′ and 3g″) is that the latter do not violate Rule 1, as the transitions remain the same. The oddness of (3g) is therefore explained by Rule 1.

Table 2 Centering analysis for discourse (3)

(3a)	Terry really goofs sometimes. C_f = {Terry}, C_p = Terry, C_b = ?, Transition = undef.
(3b)	Yesterday was a beautiful day and he was excited about trying out his new sailboat. C_f = {Terry, sailboat}, C_p = Terry, C_b = Terry, Transition = Continue
(3c)	He wanted Tony to join him in a sailing expedition. C_f = {Terry, Tony, expedition}, C_p = Terry, C_b = Terry, Transition = Continue
(3d)	He called him at 6 A.M. C_f = {Terry, Tony}, C_p = Terry, C_b = Terry, Transition = Continue
(3e)	He was sick and furious at being woken up so early. C_f = {Tony}, C_p = Tony, C_b = Tony, Transition = Smooth-shift
(3e′)	Tony was sick and furious at being woken up so early. C_f = {Tony}, C_p = Tony, C_b = Tony, Transition = Smooth-shift
(3f)	He told Terry to get lost and hung up. C_f = {Tony, Terry}, C_p = Tony, C_b = Tony, Transition = Continue
(3g)	Of course, he hadn't intended to upset Tony. C_f = {Terry, Tony}, C_p = Terry, C_b = Tony, Transition = Retain
(3g′)	Of course, Terry hadn't intended to upset Tony. C_f = {Terry, Tony}, C_p = Terry, C_b = Tony, Transition = Retain
(3g″)	Of course, Terry hadn't intended to upset him. C_f = {Terry, Tony}, C_p = Terry, C_b = Tony, Transition = Retain

Rule 2 provides a formal characterization of the perceived differences in coherence for discourse segments in terms of an ordering on transition sequences. The less frequent the shifts in a discourse, the more coherent it is. Discourse (1) above is characterized by CONTINUE transitions throughout the segment (CONTINUE, CONTINUE, CONTINUE; see Table 3) describing a highly coherent discourse, whereas discourse (2) is characterized by switches between RETAIN and CONTINUE (RETAIN, CONTINUE, RETAIN; see Table 4), describing a less coherent discourse.

Centering Theory and Anaphora Resolution

As stated right in the beginning of this article, the main goal of CT is to characterize certain aspects of local coherence. Differences in coherence result from changes in the center of attention, captured by the Centering transitions and transition ordering, and from the different expressions in which centers are realized. In particular, pronouns and definite descriptions engender different inference demands

Table 3 Centering analysis for discouse (1)

(1a)	John went to his favorite music store to buy a piano. C_f = {John, store, piano}, C_p = John, C_b = ?, Transition = undef.
(1b)	He had frequented the store for many years. C_f = {John, store}, C_p = John, C_b = John, Transition = Continue
(1c)	He was excited that he could finally buy a piano. C_f = {John, piano}, C_p = John, C_b = John, Transition = Continue
(1d)	He arrived just as the store was closing for the day. C_f = {John, store}, C_p = John, C_b = John, Transition = Continue

Table 4 Centering analysis for discourse (2)

(2a)	John went to his favorite music store to buy a piano. C_f = {John, store, piano}, C_p = John, C_b = ?, Transition = undef.
(2b)	It was a store John had frequented for many years. C_f = {store, John}, C_p = store, C_b = John, Transition = Retain
(2c)	He was excited that he could finally buy a piano. C_f = {John, piano}, C_p = John, C_b = John, Transition = Continue
(2d)	It was closing just as John arrived. C_f = {store, John}, C_p = store, C_b = John, Transition = Retain

on the hearer. CT, however, is not to be seen as a theory of anaphora resolution. The incorporation of referring expressions in the account of local coherence has led many researchers to use the CT as part of anaphora resolution algorithms. This has led to some interesting research. At the same time, it has led to some confusion in the literature associated with CT.

The first point to appreciate is that there is undoubtedly a very relevant connection between CT and anaphora resolution. As the careful reader will have deduced, the garden-path effect with the interpretation of the pronouns illustrated in discourse (3) is reminiscent of the preference ordering utilized by Sidner for the reference resolution of pronouns. In Sidner's model, the 'center of attention' is equivalent to the 'discourse focus,' and like Sidner, CT utilizes this preference for the 'center of attention' to continue over successive utterances. The relative preference of the 'actor focus' as the next center of attention is also captured with the 'preferred center' in CT. At a first look, it may seem that Sidner's use of the 'center of attention' to determine the referents of pronouns and CT's use of the same to explain how incorrect referents are assigned to pronouns result in a paradox. But a closer look shows that it isn't really so, because like CT, Sidner also allows for garden paths on the referents of pronouns by further invoking inference procedures (albeit unspecified) to check for contradictions. So Sidner's goals and CT's goals are very much alike, in that both assume similar preference for the 'initial' resolution of pronouns, which can be contradicted with further information. The difference between the two is that CT goes further to formalize the nature and difficulty of the contradictory inferences in terms of utterance pair transitions and uses the formal system as a way to compute the degree of coherence of a discourse segment.

Anaphora resolution algorithms that want to obviate the need for inference procedures and want to model the preferential rules for pronoun resolution should use the common part underlying the two described models. Sidner's inference rules for computing contradictions should be left out (or at least relegated to another interacting component), as should the part in CT that deals with the computation of coherence with the transitions and transition orderings. More formally, the common aspect of Sidner's model and CT are captured in CT with (i) the list of *forward-looking centers*, (ii) the *backward-looking center*, (iii) the *preferred center*, and (iv) Rule 1, the 'Pronoun Rule.' These data structures and rules are sufficient to set the initial preference for the referents of pronouns. Furthermore, corpus studies and studies of naturally occurring data of the form of referring expressions have shown that to a large extent speakers adhere to the preference orderings and Rule 1, so that much mileage can be achieved by building these preferences into anaphora resolution algorithms, as Sidner conjectured. However, while some anaphora resolution algorithms have used these very data structures and shown good results, others have used CT in totality, i.e., together with the transitions and transition orderings, to compute the referents of pronouns (for example, the Centering algorithm – called the BFP algorithm – for pronoun resolution in Brennan *et al.*, 1987). In addition to being theoretically misguided, the latter approach also yields contradictory results for the initial preferential resolution of pronouns (Kehler, 1997). An Optimality theory-based version of the BFP algorithm and a comprehensive overview of Centering, together with a historical development of Centering Theory and its applications, can also be found in Beaver (2004).

Unspecified Aspects of Centering

Some parameters and constants in Centering, from the perspectives of both anaphora resolution and local coherence, were left unspecified in the original

models. Two of these in particular have led to a great deal of research.

The first is determination of the preference ordering on the list of forward-looking centers or determination of relative salience of discourse entities in an utterance. This is crucial for the initial interpretation assignments for pronouns. Crosslinguistic investigation of the mechanisms that languages use to realize discourse functions like 'topic' shows that different ranking criteria need to be used for different languages. In English, relative salience is largely predicted by grammatical role, as was correctly assumed in CT. Other languages use other mechanisms. In Japanese, which uses the morphemes *wa* and *ga* to distinguish topics and subjects and special forms of the verb for marking empathy, topic- and empathy-marked entities are ranked higher than subjects. German uses word order in some syntactic contexts to indicate salience, positioning higher-ranked entities before lower-ranked ones. Other languages on which such research has been conducted include Finnish, Greek, Hindi, Italian, Russian, and Turkish.

The second is the specification of what constitutes the *utterance*, which in CT is the linguistic locus of the local attentional state. Discourse centers, both backward looking and forward looking, are computed for each utterance. That is, each utterance serves as a center update unit. In attempts to characterize the linguistic encoding of a center update unit, complications arise from complex sentence structures. Up-to-date research on this issue has suggested that complex sentences may project different center update units, depending on their internal structure.

In early theoretical work on characterizing the center update unit in Centering, it was suggested that complex sentences be broken into clauses each of which forms an autonomous center update unit, with the possible exception of relative clauses and complement clauses. Treating adverbial clauses as autonomous center update units predicts that a pronoun in a fronted adverbial clause, as in (4c), is anaphorically dependent on an entity already introduced in the immediately prior discourse and not on the subject of the main clause it is attached to.

(4b) but never 0$_i$ felt there was anything he as an individual could do about
(4c) When he$_i$ attended the Christina Anti-Communist Crusade school here about six months ago
(4d) Jim$_i$ (Kern) became convinced that he as an individual could do something constructive in the ideological battle
(4e) and 0$_i$ set out to do it

This view on backward anaphora was also professed in earlier work by Kuno, who asserted that there was no *genuine* backward anaphora: the referent of an apparent cataphoric pronoun must have appeared in the previous discourse. Empirical data later showed that this view of backward anaphora could not be maintained. Corpus studies have shown that cataphoric pronouns can appear discourse-initially.

Experimental work focusing on complex sentences of the type that includes adverbial clauses has suggested that adverbial clauses are processed as a single unit with the matrix clause. Specifically, native speakers of English tend to interpret the ambiguous subject pronoun in (5) as *the groom*, i.e., the subject of the preceding clause, even when the adverbial in the second main clause is semantically varied (*however*, *as a result*, *moreover*, *then*, etc.). This pattern contrasts with the interpretation of the subject pronoun (6), for which no consistent tendency is identified, indicating that in this case the interpretation of the pronoun is most likely determined by the semantics of the predicates of the main and adverbial clause and the relation between them.

(5) The groom hit the best man. *However*, he ...

(6) The groom hit the best man *although* he ...

Other experimental work on the interpretation of a subject pronoun following a complex sentence indicates that referents in subject position in adverbial clauses are not favored for the interpretation of a subsequent pronoun. In (7) and (8), for example, the subject pronoun is interpreted as *the conductor*, i.e., the referent of the matrix clause, even when the adverbial clause is postposed with respect to the main clause.

(7) After the tenor opened his music score the conductor sneezed three times. He ...

(8) The conductor sneezed three times after the tenor opened his music score. He ...

Data such as (5) and (6) would be a challenge for a Centering-based anaphora resolution algorithm, which processes one clause at a time, because there is no way of distinguishing between them. At the same time, these data are consistent with Centering and Centering's Pronoun Rule, under the assumption that adverbial clauses are not processed as independent update units. Under this assumption, Centering would predict the pattern observed in (5), (7), and (8). Centering's Pronoun Rule would not make a prediction for (6) with respect to the entities introduced in the main clause, because they belong to the same unit as the pronoun. Additional evidence for treating the

entire sentence as a single update unit comes from corpus work exploring various parameters that can be set for Centering and the number of Centering rules that they would violate. This type of work suggests that treating the whole complex sentence as a center update unit leads to fewer violations of the Pronoun Rule.

Studies of Centering in relative clauses present conflicting results, which need further research to be reconciled. On the one hand are discourses, like (9), that suggest that entities mentioned in relative clauses (9b) are less salient than in the main clause (9a), as indicated by the use of the subsequent use of noun phrase in (9c). In fact, a pronoun used instead of the full noun phrase would probably be interpreted as Mr. Taylor, i.e., the entity in the main clause.

(9a) Mr. Taylor$_i$, 45 years old, succeeds Robert D. Kilpatrick$_j$, 64,
(9b) who$_j$ is retiring, as reported earlier.
(9c) Mr. Kilpatrick$_j$ will remain a director.
(9d) He$_i$ . . . #He$_j$ . . .

On the other hand are discourses, like (10), that show the opposite pattern from that in (9). Such data have come from work that looked at different types of relative clauses, specifically nonrestrictive and restrictive with a definite or an indefinite head. Complementary patterns in the use of pronouns and definite descriptions shows that nonrestrictive clauses and restrictive clauses with an indefinite head pattern alike and form an autonomous (but embedded and accessible) center update unit. In (10), the subject pronoun in (10c) refers, without any garden-path effects, to the subject referent of the preceding relative clause and not to the subject referent of the main clause, indicating that in this case the relative clause probably introduces a new update unit that is accessible to (10c) for center establishment.

(10a) This Moses$_i$ was irresistible to a man like Simkin$_j$
(10b) who$_j$ loved to pity and to poke fun at the same time.
(10c) He$_j$ was a reality-instructor.

Applications of Centering Theory as a Model of Local Coherence

Some research has illustrated the appropriate and correct application of Centering Theory. The four Centering transitions shown in Table 1 define four degrees of coherence within a discourse segment. A textual segment characterized by a sequence of CONTINUE transitions demonstrates the highest degree of coherence and is perceived as a segment focusing on a single entity. Topic retains and smooth shifts to new topics are captured in the RETAIN and SMOOTH-SHIFT transitions. Indeed, numerous corpus studies have identified CONTINUE, RETAIN, and SMOOTH-SHIFT transitions. As expected, ROUGH-SHIFT transitions are rarely identified in corpora of written text, which presumably maintain a high level of coherence. An exception to this pattern has been observed in texts whose coherence is under evaluation and therefore cannot be assumed. A typical kind of this type of text is student essays. Indeed, in a study of essays written by students, it was shown that excessive number of ROUGH-SHIFT transitions per paragraph in students' essays correlated with low essay scores provided by writing experts.

A closer analysis of the essays revealed that the incoherence detected by a ROUGH-SHIFT measure was not due to violations of Centering's Pronoun Rule or other infelicitous uses of pronominal forms. The distribution of nominal and pronominal forms over ROUGH-SHIFT transitions revealed that in fact pronominal forms were avoided in ROUGH-SHIFT transitions. This observation indicates that the incoherence found in the student essays was not due to the processing load imposed on the reader to resolve anaphoric references. Instead, the incoherence in the essays was due to discontinuities caused by the introduction of a rapid succession of new, undeveloped topics with no links to the prior discourse. In other words, ROUGH-SHIFTS picked up textual incoherence due to topicx discontinuities.

Studies such as the one just described are supportive of the formulation of Centering as a model of local discourse coherence. They also show that the Centering model can be used successfully for practical applications, e.g., to improve automated systems of writing evaluation in testing and education. In fact, it has been shown that adding a Centering-based metric of coherence to an existing electronic essay scoring system (the system *e-rater* and developed at the Educational Testing Service) improved the performance of the system by better approximating human expert scores. In addition, a Centering-based system of writing evaluation has exceptional pedagogical value. This is because the model offers the capability of directing students' attention to specific locations within an essay where topic discontinuities occur. It can illuminate broken topic and focus chains within the text of an essay by drawing the student's attention to the noun phrases playing the roles of C_b's and C_p's. Supplementary instructional comments could guide the student into revising the relevant section by paying attention to topic discontinuities.

Defining Anaphora, Cataphora, and Exophora

The term 'anaphora/anaphor/anaphoric' has three distinct senses in contemporary linguistics. In the first place, it can be used for reference to a relation between two linguistic elements, in which the interpretation of one (called an anaphor) is in some way determined by the interpretation of the other (called an antecedent) (Huang, 2000a; Huang, 2004). Linguistic elements that can be employed to encode an anaphoric relation in this general sense range from gaps (or empty categories) through reflexives to various reference-tracking systems like gender/class, switch function and switch reference. Second, the term can be used in Chomsky's generative syntax to refer to an NP with the features [+anaphor, −pronominal], as against a pronominal, an NP with the features [−anaphor, +pronominal]. Thus the reflexive in (1) is treated as an anaphor, and the (other-referring) pronoun in (2) as a pronominal in the Chomskyan sense.

(1) Russell$_1$ admired himself$_1$.
(2) Russell$_1$ admired him$_2$.

Third, the term can be used to refer to an anaphor whose antecedent comes earlier, as in (3), as opposed to 'cataphora/cataphor/cataphoric,' where the antecedent comes later (4).

(3) After John$_1$ got promoted, his$_1$ salary went up.
(4) After he$_1$ got promoted, John's$_1$ salary went up.

Both anaphora and cataphora in this sense can be subsumed under the term 'endophora/endophor/endophoric,' referring to the relation in which the anaphor/cataphor and its antecedent are within what is said or written. In contrast, by the term 'exophora/exophor/exophoric' is meant that the 'antecedent' of an anaphor, or more accurately a deictic expression, lies outside what is said or written. This is illustrated in (5).

(5) (Referents in the physical context, and with selecting gestures) He$_1$'s not the managing director. He$_2$ is.

NP-Anaphora

In terms of syntactic category, anaphora can be divided into two main categories: NP-including $\overline{\text{N}}$-anaphora, and VP-anaphora. In an NP-anaphoric relation, both the anaphor and its antecedent are NPs, and both are potentially referring expressions, as in (6). NP-anaphora can be expressed by gaps, pronouns, reflexives, names, and descriptions. By contrast, in an $\overline{\text{N}}$-anaphoric relation, both the anaphor and its antecedent are an $\overline{\text{N}}$ rather than an NP, and neither is a potentially referring expression, as in (7). Linguistic elements that can be used as an $\overline{\text{N}}$-anaphor include gaps, pronouns and nouns.

(6) Alain Robert$_1$ said that he$_1$ enjoyed scaling the world's skyscrapers with no safety net.
(7) John's brother is an anti-war campaigner, and Bill's Ø is an anti-globalization activist.

Anaphora can be intrasentential, in which case the anaphor and its antecedent occur within a single simplex or complex sentence. It can also be discoursal, in which case the anaphor and its antecedent cross sentence boundaries (see Huang, 2000a, 2000b for discussion of discourse anaphora). Regarding intrasentential NP-anaphora, three main theoretical approaches can be identified: syntactic, semantic, and pragmatic.

The Syntactic Approach

The central idea underlying a syntactic analysis is that anaphora is largely a syntactic phenomenon, and as such references must be made to conditions and constraints that are essentially syntactic in nature. This approach is best represented by Chomsky's (1981, 1995) binding theory within the principles-and-parameters theory and its minimalist descendant.

Chomsky distinguishes two types of abstract feature for NPs: anaphors and pronominals. An anaphor is a feature representation of an NP which must be referentially dependent and which must be bound within an appropriately defined minimal syntactic domain; a pronominal is a feature representation of an NP which may be referentially dependent but which must be free within such a domain. Interpreting anaphors and pronominals as two independent binary features, Chomsky hypothesizes that one ideally expects to find four types of NP in a language – both overt and nonovert.

(8) Chomsky's typology of NPs

	Overt	Empty
a. [+anaphor, −pronominal]	reflexive/ reciprocal	NP-trace
b. [−anaphor, +pronominal]	pronoun	*pro*

c. [+anaphor, +pronominal]	–	PRO
d. [−anaphor, −pronominal]	name	*wh*-trace

Of the four types of overt NP listed above, anaphors, pronominals, and r[eferential]-expressions are subject to binding conditions A, B, and C respectively.

(9) Chomsky's binding conditions
A. An anaphor is bound in a local domain.
B. A pronominal is free in a local domain.
C. An r-expression is free.

Binding is defined on anaphoric expressions in configurational terms, appealing to purely structural concepts like c-command, government, and locality. The binding theory accounts for the syntactic distribution of anaphoric expressions in (10). It is also applicable to three of the four empty categories listed in (8): NP-trace, *pro*, and *wh*-trace, but that work will not be reviewed here (cf. Huang, 1992, 1995).

(10) a. Russell$_1$ admired himself$_1$.
b. Russell$_1$ admired him$_2$.
c. Russell$_1$ admired Russell$_2$.

There are, however, serious problems at the very heart of Chomsky's binding theory. Cross-linguistically, the distribution of reflexives violates binding condition A in both directions: on the one hand, a reflexive can be bound outside its local domain (the so-called long-distance reflexive or anaphor), as in Chinese, Russian and Telugu (see 11); on the other, it may not be bound within its local domain, as in Dutch and Norwegian (see 12).

(11) (Chinese) (Modern Chinese)
Xiaoming gaosu Xiaohua Xiaolan bu xihuan ziji.
Xiaoming tell Xiaohua Xiaolan not like self
'Xiaoming$_1$ tells Xiaohua$_2$ that Xiaolan$_3$ does not like self$_{1/*2/3}$.'

(12) (Norwegian) (Hellan, 1988)
*Jon foraktet seg.
Jon despises self
'Jon despises himself.'

Binding condition B is also frustrated, for in many of the world's languages (such as Catalan [Catalan-Valencian-Balear], Gumbaynggir [Kumbainggar] and Haitian Creole [Haitian Creole French]), a pronominal can be happily bound in its local domain. Next, given Chomsky's formulation of binding conditions A and B, it is predicted that anaphors and pronominals will be in strict complementary distribution, because the two binding conditions are precise mirror images of each other. But this predicted complementarity cannot be maintained. Even in a 'syntactic' language such as English, it is not difficult to find syntactic environments where the complementarity breaks down (see 13).

(13) a. Blair$_1$ saw a picture of himself$_1$/him$_1$ in the *Times*.
b. Mary$_1$ saw a snake near herself$_1$/her$_1$.
c. [Pavarotti and Domingo]$_1$ adore each other's$_1$/their$_1$ performances.
d. Pavarotti$_1$ said that tenors like himself$_1$/him$_1$ would not sing operas like that.

Finally, even a cursory inspection of languages such as English, Korean, and Vietnamese indicates that binding condition C cannot be taken as a primitive of grammar, either (see Huang, 1996, 2000a, 2004 for further discussion).

The Semantic Approach

In contrast to the 'geometric,' syntactic approach, the semantic approach views anaphora as essentially a semantic phenomenon. Accordingly, binding is defined in argument structure terms. Reinhart and Reuland's (1993) theory of reflexivity, for example, belongs to this camp.

(14) Reinhart and Reuland's binding conditions:
A. A reflexive-marked syntactic predicate is reflexive.
B. A reflexive semantic predicate is reflexive-marked.

(15) Reinhart and Reuland's typology of overt NPs

	SELF	SE	pronoun
Reflexivizing function	+	−	−
Referential independence	−	−	+

SELF = a morphologically complex reflexive, e.g., *himself*, *zichzelf*
SE = a morphologically simplex reflexive, e.g., *ziji*, *zich*, *seg*.

In Reinhart and Reuland's view, reflexivity is not a property of NPs but of predicates. The binding theory is designed not to capture the mirror image distribution of anaphors and pronominals, but to regulate the domain of reflexivity for a predicate. More specifically, what the theory predicts is that if a predicate is lexically reflexive, it may not be reflexive-marked by a morphologically complex SELF anaphor in the overt syntax. On the other hand, if a predicate is not lexically reflexive (that is, if it contains a semantic predicate), it may become reflexive only via the marking of one of its coarguments by such an anaphor. This explains why (12) is ungrammatical. Since the predicate in (12) is not lexically reflexive, it

must be reflexive-marked in order to comply with Reinhart and Reuland's binding condition B. But the SE-anaphor *seg* is not a reflexivizer, and consequently cannot reflexive-mark the predicate, hence the ungrammaticality of (12).

Reinhart and Reuland's theory, however, is not without problems of its own. First, cross-linguistic evidence has been presented that marking of reflexivity is not limited to the two ways identified by Reinhart and Reuland. In addition to being marked lexically and syntactically, reflexivity can also be indicated morphologically. Secondly, more worrisome is that the central empirical prediction of the reflexivity analysis, namely, only a reflexive predicate can and must be reflexive-marked, is falsified in both directions. On the one hand, a predicate that is both syntactically and semantically reflexive can be nonreflexive-marked in the sense of Reinhart and Reuland, as in (16); on the other, a nonreflexive predicate can be reflexive-marked, as in (17) (see Huang, 2000a, 2004 for further discussion).

(16) (Icelandic)
Jon elskar sig.
Jon loves self
'Jon loves himself.'

(17) (Chinese) (Mandarin Chinese)
Xiaoming shuo taziji hen xihuan yinyue.
Xiaoming say 3SGself very like music
'Xiaoming says that he likes music very much.'

Note also that neither Chomsky's binding theory nor Reinhart and Reuland's reflexivity theory is designed to say anything about the anaphoric relations in examples like (3), (4), and (6).

The Pragmatic Approach

As an alternative to the syntactic and semantic approaches, there is the pragmatic approach. The most influential of the pragmatic analyses is the neo-Gricean pragmatic theory of anaphora developed by Levinson (1987, 1991, 2000)and Huang (1991, 1994, 2000a, 2000b, 2004). Central to this theory is the assumption that anaphora is essentially pragmatic in nature, though the extent to which anaphora is pragmatic varies typologically. Consequently, anaphora can largely be determined by the systematic interaction of some general neo-Gricean pragmatic principles such as Levinson's (2000) Q-, I-, and M-principles (18), depending on the language user's knowledge of the range of options available in the grammar, and of the systematic use or avoidance of particular anaphoric expressions or structures on particular occasions.

(18) Levinson's Q-, I- and M-principles (simplified)
a. The Q-principle
Speaker: Do not say less than is required (bearing I in mind).
Recipient: What is not said is not the case.
b. The I-principle
Speaker: Do not say more than is required (bearing Q in mind).
Recipient: What is generally said is stereotypically and specifically exemplified.
c. The M-principle
Speaker: Do not use a marked expression without reason.
Recipient: What is said in a marked way is not unmarked.

Applying the Q-, I-, and M-principles to the domain of anaphoric reference, we can derive a general neo-Gricean pragmatic apparatus for the interpretation of various anaphoric expressions in (19).

(19) Huang's (2000a, 2004) revised neo-Gricean pragmatic apparatus (simplified)
i. The use of an anaphoric expression x I-implicates a local coreferential interpretation, unless (ii) or (iii).
ii. There is an anaphoric Q-scale $<x, y>$, in which case the use of y Q-implicates the complement of the I-implicature associated with the use of x in terms of reference.
iii. There is an anaphoric M-scale $\{x, y\}$, in which case the use of y M-implicates the complement of the I-implicature associated with the use of x, in terms of either reference or expectedness.

Needless to say, any interpretation generated by (19) is subject to the general consistency constraints applicable to Gricean conversational implicatures. These constraints include world knowledge, contextual information, and semantic entailments.

Substantial cross-linguistic evidence has been presented to show that empirically the revised neo-Gricean pragmatic theory of anaphora is more adequate than both a syntactic and a semantic approach. Regarding (10), on this account, Chomsky's binding conditions B and C can be reduced to pragmatics. In somewhat simplified terms, this can be achieved in the following way. If binding condition A is taken to be either grammatically constructed (as in English-type, syntactic languages) or pragmatically specified (as in Chinese [Mandarin Chinese]-type, pragmatic languages), then binding condition B is the direct result of the application of the Q-principle. Given this principle, the use of a semantically weaker pronoun where a semantically stronger

reflexive could occur gives rise to a conversational implicature which conveys the negation of the more informative, coreferential interpretation associated with the use of the reflexive, as in (10b). By the same reasoning, binding condition C can also be eliminated. Wherever a reflexive could occur, the use of a semantically weaker proper name Q-implicates the non-applicability of the more informative, coreferential interpretation associated with the use of the reflexive. This is exactly what has happened in (10c). Moreover, the revised neo-Gricean pragmatic theory can provide an elegant account of many of the anaphoric patterns that have always embarrassed a generative analysis, such as the cases where a pronoun is bound in its local domain. It can also accommodate examples like (3), (4), and (6), which lie outside the scope of either Chomsky's binding theory or Reinhart and Reuland's reflexivity theory. Next, from a conceptual point of view, the revised neo-Gricean pragmatic theory of anaphora has important implications for current thinking about universals, innateness, and learnability.

VP-Anaphora

A Typology of VP-Anaphora

There are five types of VP-anaphora. First, VP-ellipsis, in which the VP of the second and subsequent clauses is somewhat elided, as in (20). Second, gapping, in which some element (typically a repeated, finite verb) of the second and subsequent conjuncts of a coordinate construction is dropped, as in (21). Third, sluicing, which involves the deletion of an IP within an embedded CP, resulting in an elliptical construction where an IP contains an embedded interrogative CP consisting only of a *wh*-phrase, as in (22). Fourth, stripping – an elliptical construction in which the ellipsis clause usually contains only one constituent, as in (23). And finally, there is null complement anaphora – an elliptical construction in which a VP or IP complement of a verb is omitted, as in (24).

(20) John adores his girlfriend, and Peter does, too.
(21) Reading maketh a full man; conference a ready man; and writing an exact man. (Bacon)
(22) Nigel wrote something about the internet, but I don't know what.
(23) Pavarotti will sing *Nessun Dorma* again, but not at Covent Garden.
(24) Lucy wanted to sit on a tree overhanging the river, but her mother didn't approve.

VP-Ellipsis: Properties, Issues, and Analyses

Of the five types of VP-anaphora listed above, VP-ellipsis has attracted the most attention.

Properties VP-ellipsis has a number of distinct properties, notably: it can occur either in a coordinate or subordinate clause; it engenders a sloppy reading; it exhibits the locality effect on the sloppy reading; the sloppy reading is subject to the c-command condition; VP-ellipsis may operate across sentence boundaries; it may take a pragmatic antecedent; and it may have a split antecedent.

Issues Two issues are of particular interest in the analysis of VP-ellipsis. The first and more traditional one is concerned with the availability and distribution of the strict and sloppy interpretations. This can be illustrated by a consideration of (20) above. In (20), the second, elided conjunct is ambiguous. It can be understood either in the manner of (25a) – the so-called strict reading, or in the manner of (25b) – the so-called sloppy reading.

(25) a. John adores John's girlfriend, and Peter adores John's girlfriend.
b. John adores John's girlfriend, and Peter adores Peter's girlfriend.

Second, there are what Fiengo and May (1994) called the eliminative puzzles – the question of why VP-ellipsis reduces the number of possible interpretations of sentences relative to their nonelided counterparts. Of particular concern here are three types of eliminative puzzle: the many-pronouns puzzle, as in (26), the many-clauses puzzle, as in (27), and the Dahl puzzle, as in (28).

(26) John said that he adored his girlfriend, and Peter did, too.
(27) John adores his girlfriend, Peter does, too, but David doesn't.
(28) John thinks that he is intelligent, Peter does, too, but his girlfriend doesn't.

Analyses Two general approaches can be identified, syntactic and semantic. Central to the syntactic analyses is the claim that VP-ellipsis can best be resolved at some level of syntactic structure. On this view, the interpretation of VP-ellipsis involves the reconstruction of the target clause on the basis of the syntactic structure of the source clause. Semantic representations which are derived syntactically are then assigned to the elided VP in a manner parallel to the antecedent VP. Currently this approach is best represented by Fiengo and May (1994). By way of contrast to the syntactic, reconstructionist approach, the semantic approach takes the view that VP-ellipsis can best be resolved at a purely semantic level of representation. Under this approach, the interpretation of VP-ellipsis bears on the identification of a property

of the antecedent VP and the assignment of this property to the elided VP. Dalrymple, Shieber and Pereira (1991), for instance, belong to this camp.

Also noteworthy is a second distinction in the study of VP-ellipsis that is independent of the syntactic/semantic approach distinction we have just seen. Dalrymple, Shieber and Pereira (1991) noted that a distinction can be made between those analyses which trace the strict/sloppy dichotomy to an ambiguity in the representation of the source clause and those which attribute it to the process of recovering a property or relation for the target clause. Let us call the first type the source ambiguity analysis, and the second type the process ambiguity analysis. Next, regarding the source ambiguity account, within the syntactic camp, the ambiguity of interpretation can be derived in a partially interpretative way either by deleting the phrase structure of the target clause under the condition of identical semantic interpretation, or by copying the syntactic structure of the source clause to the target clause but requiring identical semantic representation for the two VPs. Within the semantic camp, the multiplicity of interpretation can be obtained in a purely interpretative manner by assuming an unambiguous syntactic analysis of the source clause (see Huang, 2000a for further discussion).

In addition to the syntactic and semantic approaches mentioned above, Kehler (2002) has recently put forward an analysis which is based on the notion of discourse coherence. According to this analysis, VP-ellipsis can partially be accounted for in terms of various neo-Humean coherence relations such as resemblance, cause–effect, and contiguity.

Logophoricity

Defining Logophoricity

Logophoricity can be regarded as a special case of NP-anaphora. The term 'logophoricity' is used for reference to the phenomenon whereby the point of view of an internal protagonist of a sentence or discourse, as opposed to that of the current, external speaker, is being reported using some morphological and/or syntactic means (e.g., Huang, 2000a, 2002). The term 'point of view' is employed here in a technical sense and is intended to encompass words, thoughts, knowledge, emotion, and perception. The concept of logophoricity was introduced in the study of African languages such as Aghem, Ewe and Tuburi (Tupuri) (see Hagège, 1974; Clements, 1975), where there is a separate paradigm of logophoric pronouns which is used for such a purpose. By way of illustration, consider (29) and (30) from Donno Sɔ, taken from Culy (1994).

(29) Oumar Anta inyemɛñ waa be gi.
Oumar Anta LOG-ACC seen AUX said
'Oumar$_1$ said that Anta$_2$ had seen him$_1$.'

(30) Oumar Anta woñ waa be gi.
Oumar Anta 3SG-ACC seen AUX said
'Oumar$_1$ said that Anta$_2$ had seen him$_3$.'

In (29) the use of the logophoric pronoun encodes a coreferential reading between it and the matrix subject, thus reporting Oumar's speech from his perspective. By contrast, in (30) the employment of the regular pronoun indicates a disjoint reference, hence reporting Oumar's speech from the point of view of the current, external speaker.

Cross-Linguistic Marking of Logophoricity

Cross-linguistically, logophoricity may be morphologically and/or syntactically expressed by one or more of the following mechanisms: (i) logophoric pronouns, as in (29) above; (ii) logophoric addressee pronouns, as in (31); (iii) logophoric verbal affixes, as in (32); and (iv) long-distance reflexives, as in (11) above.

(31) Logophoric addressee pronouns (Mapun, Frajzyngier, 1985)
n- sat n-wur taji gwar dim n Kaano.
I say BEN-3SG not ADDR go PREP Kano
'I told him$_1$ that he$_1$ may not go to Kano.'

(32) Logophoric verbal affixes (Gokana; Hyman and Comrie, 1981)
à nyíma kɔ aè dɔ-ɛ.
he know that he fell-LOG
'He$_1$ knows that he$_1$ fell.'

Logophoric marking devices (i)–(iii) are found largely in African languages, and logophoric marking mechanism (iv) is located in a wide range of languages throughout the world. Furthermore, these devices can be ranked according to the following hierarchy (Huang, 2000a, 2002).

(33) Hierarchy of grammatical mechanisms for logophoric marking
a. Logophoric pronouns/addressee pronouns/verbal affixes [+logophoric, +coreference]
b. Long-distance reflexives [±logophoric, +coreference]

What (33) basically says is this: for logophoric marking, a logophoric pronoun, addressee pronoun, or verbal affix will be used if there is one; otherwise, a long-distance reflexive will be used. A second point to be borne in mind is that logophoricity and coreference are two distinct, though closely related, notions; logophoricity entails coreference, but not vice versa.

A Typology of Languages with Respect to Logophoricity

Following suggestions made by von Roncador (1992) and Culy (1994), languages can be grouped into three types with respect to logophoricity: full or pure logophoric languages – languages which have special morphological and/or syntactic forms that are employed only in logophoric domains (e.g., Babungo [Vengo], Pero, and Ekepeye [Ekpeye]); nonlogophoric languages – languages which have no such morphological and/or syntactic forms (e.g., Arabic, English, and Mambar); and semi- or mixed logophoric languages – languages which either allow logophors to be used for nonlogophoric purposes (e.g., Igbo, Idoma, and Yoruba) or allow the extended use of reflexives in logophoric contexts (e.g., Bangla [Bengali], Icelandic, and Japanese). It is particularly interesting, as Culy (1994) observed, that while logophoric languages are found in many places throughout the world, full or pure logophoric languages seem to be found only in Africa. Furthermore, while full or pure logophoric languages are not in a contiguous area, logophoric languages as a whole are in a contiguous area. This geographic distribution of logophoric languages is fascinating as well as surprising, and for the time being, remains unexplained.

Some Implicational Universals with Respect to Logophoricity

In Huang (2000a, 2002), a number of implicational universals with respect to logophoricity are proposed. The first of these is concerned with the person distinction of logophoric pronouns.

(34) Person hierarchy for logophoric pronouns
3 > 2 > 1
First-person logophoric pronouns imply second-person logophoric pronouns, and second-person logophoric pronouns imply third-person logophoric pronouns.

Given (34), it is predicted that in all languages with logophoric pronouns, logophoric pronouns can be third-person; in some, they can also be identified as second-person; in a few, they can be distinguished as first-person as well (see also Hyman and Comrie, 1981; Wiesemann, 1986). This pattern of person distinction holds also for logophoric long-distance reflexives. As pointed out in Huang (2000a, 2002), there is a functional/pragmatic explanation for (34): for referential disambiguity, the third-person distinction is the most, and the first-person distinction the least, useful, with the second-person distinction lying in between, for third-person is closer to nonperson than either first- or second-person. It follows therefore that the fact that first-person logophoric pronouns are rare in languages is hardly surprising, given that logophoric pronouns are one of the (most common) devices that the current, external speaker (which is encoded usually in terms of a first-person pronoun) utilizes in reflecting the perspective of anyone else (usually an internal protagonist) but him- or herself.

Second, there is the implicational universal for the number distinction of logophoric pronouns.

(35) Number hierarchy for logophoric pronouns
Singulars > plurals
Plural logophoric pronouns imply singular logophoric pronouns.

The implicational universal in (35) summarizes the general pattern of number specification for logophoric pronouns. While all languages with logophoric pronouns allow singular logophoric pronouns, only some permit plural logophoric pronouns as well (see also Hyman and Comrie, 1981; Wiesemann, 1986). This pattern of number specification holds also for logophoric long-distance reflexives.

Next, mention should be made of logocentric triggers, namely those NPs that can act as an antecedent for a logophoric pronoun or logophoric long-distance reflexive. First, logocentric triggers are generally constrained to be a core argument of the logocentric predicate of the matrix clause. Secondly, they are typically subjects. However, logocentric triggers can also be some other, nonsubject argument, provided that this argument represents the 'source' of the proposition or the 'experience' of the mental state that is being reported. Two types of construction are particularly common in African logophoric languages. The first involves the predicate 'hear from.' The second involves 'psychological' predicates expressing emotional states and attitudes, of which the 'experiencer' serves as direct object or object of preposition. (36) is the implicational universal for logocentric triggers.

(36) Hierarchy for logocentric triggers
Surface structure: subject > object > others
Semantic role: agent > experiencer/benefactive > others

The higher an NP is on the hierarchy, the more likely it will function as an antecedent for a logophoric pronoun or a logophoric long-distance reflexive (see also Hyman and Comrie, 1981). Given that the subject of the matrix clause is typically the NP that is the highest on the hierarchy (and, incidentally, the most animate), it is hardly surprising that it is the typical antecedent for a logophoric pronoun or a logophoric long-distance reflexive.

Taken together, the above three hierarchies predict that the most basic, unmarked pattern of logophoric

marking is one which encodes logophoricity by the use of a third-person, singular, logophoric pronoun which refers to a human subject.

Finally, it should be pointed out that logophoric pronouns or logophoric long-distance reflexives usually occur in a logophoric domain, that is, a stretch of discourse in which the internal protagonist's perspective is being represented. The logophoric domain is commonly created by a logocentric licenser, which consists mainly of a logocentric predicate. Logocentric predicates can be distinguished largely on a semantic basis. The most common types of logocentric predicates are predicates of speech and thought. But other types of predicates, such as those of mental state, knowledge, and direct perception, can also trigger a logophoric domain. While languages differ in allowing precisely which type of predicate to function as a logocentric licenser, cross-linguistically there exists an implicational universal for logophoric predicates (see also Stirling, 1993; Culy, 1994; Huang, 1994, 2000a).

(37) An implicational universal for logocentric predicates
Speech predicates > epistemic predicates > psychological predicates > knowledge predicates > perceptive predicates

What (37) basically states is this: if a language allows (some) predicates of one class to establish a logophoric domain, then it will also allow (some) predicates of every class higher on the hierarchy to do the same. Thus, if a language has logophoric marking with predicates of, say, psychological state, then it will necessarily have it with predicates of thought and communication.

Anaphora: Philosophical Aspects

J King, University of Southern California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Anaphora is the phenomenon whereby an expression, which is called a **proform** (e.g., 'he' [pro**noun**], 'so' [pro**adjective**]), is interpreted in light of another expression in its immediate linguistic context, which is called the proform's **antecedent**. In this article, I will confine my attention to anaphoric pronouns, since they are the instances of anaphora that are of most interest to philosophers and linguists. A simple example of an anaphoric pronoun is the following (where 'Rebecca' is the antecedent of 'she'):

(1) Rebecca left and she was angry.

Simple instances of anaphora such as (1), in which an anaphoric pronoun has a referring expression as its antecedent, are not of much interest to philosophers and linguists. The reason is that such cases seem easy to understand. The anaphoric pronoun simply refers to whatever its antecedent does.

Another sort of case in which the behavior of an anaphoric pronoun is well understood, and hence not of much current interest to philosophers and linguists, is a case of the following sort (on the reading on which 'she' has 'Every professor' as its antecedent):

(2) Every professor believes she is smart.

In such cases, it is widely held that the pronoun is functioning as a variable bound by its quantifier antecedent. Thus, (2) could be represented more perspicuously as:

(2a) [Every professor: x][x believes x is smart]

where the third occurrence of 'x' corresponds to the pronoun. Since the pronoun behaves like a variable in predicate logic, and since the behavior of such variables is well understood, most philosophers and linguists do not worry about such cases.

The interest of linguists and philosophers in anaphora derives from the fact that there are instances of anaphora in which the anaphoric expression cannot be understood as an expression referring to whatever its antecedent does (as in [1]) nor as a variable bound by its quantifier antecedent (as in [2]). Let's call such cases instances of **puzzling anaphora**. The question then arises as to how puzzling anaphora should be understood semantically. As will be seen, there are a number of competing proposals. We shall discuss two kinds of puzzling anaphora here. The first instance of puzzling anaphora is a case in which a pronoun has a quantifier antecedent in another sentence. Anaphora of this sort is often called **discourse anaphora**. Here are two examples:

(3) Few students passed the exam. They studied hard.

(4) A woman is following Glenn. She is from the IRS.

For the moment, let's concentrate on (3). There are at least two reasons for thinking that the pronoun in (3) is not a variable bound by its quantifier antecedent. Both reasons are discussed by Evans (1977). The first is that such a treatment clearly yields the wrong truth conditions for examples like (3). If 'they' is a bound variable in (3), the two sentences of (3) together should be equivalent to:

(3a) Few students: x (x passed the exam and x studied hard)

But this is obviously incorrect, since (3) entails that few students passed the exam, but (3a) does not (it would be true if many students passed, but few both passed and studied hard).

Second, it is generally thought that the scope of a quantifier cannot extend beyond the sentence in which it occurs. If that is correct, then the pronoun in (3) falls outside of the scope of its quantifier antecedent and so cannot be bound by it.

Further, the pronoun in (3) cannot be understood as referring to whatever its antecedent does, since its antecedent is a quantifier and not a referring term at all. Since the pronoun cannot be understood as a bound variable nor as an expression that refers to whatever its antecedent does, the question arises as to how we should understand it semantically.

A second kind of puzzling anaphora is called **donkey anaphora** and it comes in two varieties. The first I will call **conditional donkey anaphora**:

(5) If Sarah owns a donkey, she beats it.

(where 'it' is anaphoric on 'a donkey'). The second I will call **relative clause donkey anaphora**:

(6) Every woman who owns a donkey beats it.

(where 'it' is anaphoric on 'a donkey'). On the readings we are concerned with, neither (5) nor (6) is talking about any particular donkey, and so the pronoun 'it' cannot be a term referring to a particular donkey. Further, in the case of (5), all independent evidence available suggests that a quantifier cannot take wide scope over a conditional and bind variables in its consequent (*'If John owns every donkey$_i$, he beats it$_i$'). This suggests that the (apparent) quantifier 'a donkey' in (5) cannot bind the pronoun in the consequent. In addition, even if 'a donkey' could magically do this in

(5), assuming it is an existential quantifier, we still would not get the intuitive truth conditions of (5), which require that Sarah beat every donkey she owns. Similarly, the independent evidence available suggests that quantifiers cannot scope out of relative clauses (*'A man who owns every donkey$_i$ beats it$_i$'), and so again the pronoun in (6) is not within the scope of its quantifier antecedent and so is not bound by it. Thus, the pronouns in both conditional and relative clause donkey anaphora cannot be understood as referring expressions nor as bound variables.

So we have two kinds of puzzling anaphora, discourse anaphora and donkey anaphora. In neither case can the anaphoric pronouns be understood as bound variables or as expressions referring to whatever their antecedents refer to. The question is: how should we understand such cases of anaphora semantically? A number of theories have been developed to answer this question. Sketches of four prominent theories of puzzling anaphora are given here. Because the theories are technical and sophisticated, only the barest sketch can be given of them. Readers interested in more detail should consult papers cited in the bibliography.

The first theory of puzzling anaphora we will consider is **Discourse Representation Theory** or **DRT**. Though this name for the view comes from Kamp (1981), Heim (1982) independently developed a very similar view. Here I will be neutral between the somewhat different Heim and Kamp formulations. DRT claims that the indefinites in discourse anaphora like (4) ('A woman') and donkey anaphora like (5) and (6) ('a donkey') are not quantifiers. Instead they are really predicates that introduce free variables. The anaphoric pronouns are variables in such cases too. The apparent existential force of the indefinite in (4) results from default existential quantification over free variables. In (5), the semantics of the pronoun interacts with the semantics of the conditional to yield the result that the sentence is true iff Sarah beats every donkey she owns. In (6), the quantifier 'Every woman' 'unselectively binds' both the woman variables in logical form and the variables introduced by 'a donkey' and 'it'. So in (6), the anaphoric pronoun is bound after all, but not by its antecedent ('a donkey').

Descriptive Approaches to anaphora have been formulated by Evans (1977), Parsons (1978), Davies (1981), Neale (1990), and Heim (1990). On approaches of this sort, anaphoric pronouns in puzzling anaphora in some sense are interpreted as definite descriptions. Thus, the pronoun in (4) is interpreted as 'the woman following Glenn'. Similar remarks apply to the pronouns in (5) and (6). Here different accounts are given as to why and how (5) an (6) are true iff Sarah/Every woman beats every donkey she owns. For example, Neale (1990) claims that in such cases, the pronouns are interpreted as 'numberless descriptions,' which are essentially universal quantifiers. This yields the truth conditions mentioned. For a different approach, see Heim (1990).

The Context-Dependent Quantifier Approach (CDQ) is formulated and defended by King (1987, 1991, 1994, 2005) and Wilson (1984). On this approach, pronouns in instances of puzzling anaphora are themselves quantifiers. The forces (universal or existential), restrictions (what the quantifiers range over – e.g., 'every student' ranges over students) and relative scopes are determined by features of their linguistic contexts. Thus, according to CDQ, the anaphoric pronouns in puzzling anaphora are contextually sensitive devices of quantification. The precise natures of the quantifiers they express are determined by features of their linguistic contexts. In (4), CDQ holds that the pronoun expresses the existential quantifier normally expressed outside of any context by the indefinite 'a woman following Glenn'. Similar remarks apply to (5) and (6), except that the semantics of the conditional interacts with the pronoun *qua* quantifier to get the proper reading of (5) (see King, 2005); and in (6), the pronoun *qua* quantifier takes narrow scope with respect to the universal quantifier 'Every woman' (because its antecedent does as well).

Finally, there are **Dynamic Logic Accounts (DL)** of puzzling anaphora, originally formulated by Groenendijk and Stokhof, (1991), with different versions put forward by Chierchia (1995) and Kanazawa (1994a and 1994b). The key claim of such accounts is that quantifiers can semantically bind pronouns even if those pronouns do not occur in their syntactic scopes. So, despite appearances, the pronouns in (4), (5), and (6) are semantically bound by their quantifier antecedents. DL also makes novel claims about the semantics of conditionals and universal quantification to get the truth conditions of (5) and (6) to come out right.

At this stage of inquiry, it is fair to say that there is no consensus on which of the above-mentioned theories is correct. Each of the theories faces some difficulties and it is difficult to determine which theory is most successful. It is to be hoped that future research will shed more light on the proper theory of puzzling anaphora.

Anatomical Asymmetries Versus Variability of Language Areas of the Brain

O Selnes, Johns Hopkins University, Baltimore, MD, USA
H A Whitaker, Northern Michigan University, Marquette, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Significant individual variability in the volume, weight, and morphology of the human brain has been recognized since the first detailed studies were performed as early as a century ago. Attempts to relate such variability in the size of the brain to functional properties have generally been predicated on the phrenological principle that a larger brain is a better brain. Despite improvements in the methods used for quantifying brain volume, evidence in support of this hypothesis remains weak. In addition to variability in overall brain volume, there is also variability in the degree of asymmetry between the two hemispheres of the brain. Mild asymmetry of paired structures is a common feature of all aspects of human anatomy, including the well-documented differences between the left and right hemispheres of the brain. Asymmetries favoring regions of the dominant (left) hemisphere known to be important for speech and language functions have been interpreted to reflect some as yet to be defined morphological marker of cerebral language dominance. The presence of similar asymmetries in nonhuman primates, however, has led some to question the relevance of such anatomical asymmetries for language functions. Anatomical differences between the left and right hemispheres of the brain have also been identified for regions not involved with speech and language functions. Such differences are present at multiple levels, including differences in overall volume and weight between the two hemispheres, and more regional asymmetries including specific subdivisions of the four major lobes of the brain, as well as in subcortical regions.

Individual Variability

Overall Brain Volume

Most earlier studies of the individual variability in the size, weight, and morphology of the human brain were based on autopsy materials. Such data were limited by several factors, including an autopsy bias towards older and less healthy individuals. With the advent of magnetic resonance imaging (MRI), recent studies of individual variability of the anatomy of the human brain have avoided these limitations. On the basis of volumetric MRI measures, the average total brain volume (excluding cerebrospinal fluid and the meningeal coverings) has been in the range 1250 to 1290 cm^3 for well-nourished males of predominantly European ancestry. For women, average brain volumes are approximately 130 cm^3 less. These MRI-based whole-brain volume estimates are generally smaller than previous measurements based on post-mortem materials. Overall brain volume is closely related to body weight or body mass index. Although

Anatomical Asymmetries Versus Variability of Language Areas of the Brain

O Selnes, Johns Hopkins University, Baltimore, MD, USA
H A Whitaker, Northern Michigan University, Marquette, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Significant individual variability in the volume, weight, and morphology of the human brain has been recognized since the first detailed studies were performed as early as a century ago. Attempts to relate such variability in the size of the brain to functional properties have generally been predicated on the phrenological principle that a larger brain is a better brain. Despite improvements in the methods used for quantifying brain volume, evidence in support of this hypothesis remains weak. In addition to variability in overall brain volume, there is also variability in the degree of asymmetry between the two hemispheres of the brain. Mild asymmetry of paired structures is a common feature of all aspects of human anatomy, including the well-documented differences between the left and right hemispheres of the brain. Asymmetries favoring regions of the dominant (left) hemisphere known to be important for speech and language functions have been interpreted to reflect some as yet to be defined morphological marker of cerebral language dominance. The presence of similar asymmetries in nonhuman primates, however, has led some to question the relevance of such anatomical asymmetries for language functions. Anatomical differences between the left and right hemispheres of the brain have also been identified for regions not involved with speech and language functions. Such differences are present at multiple levels, including differences in overall volume and weight between the two hemispheres, and more regional asymmetries including specific subdivisions of the four major lobes of the brain, as well as in subcortical regions.

Individual Variability

Overall Brain Volume

Most earlier studies of the individual variability in the size, weight, and morphology of the human brain were based on autopsy materials. Such data were limited by several factors, including an autopsy bias towards older and less healthy individuals. With the advent of magnetic resonance imaging (MRI), recent studies of individual variability of the anatomy of the human brain have avoided these limitations. On the basis of volumetric MRI measures, the average total brain volume (excluding cerebrospinal fluid and the meningeal coverings) has been in the range 1250 to 1290 cm^3 for well-nourished males of predominantly European ancestry. For women, average brain volumes are approximately 130 cm^3 less. These MRI-based whole-brain volume estimates are generally smaller than previous measurements based on post-mortem materials. Overall brain volume is closely related to body weight or body mass index. Although

brain sizes at the extremes of the normal distribution (macro- and microcephaly) may be associated with cognitive abnormalities, the evidence that variations **within** the average range are correlated with intelligence or other cognitive functions remains difficult to interpret. Modest positive correlations between full-scale IQ and total gray matter volume have been reported in some studies (Bernard *et al.*, 1993), suggesting that greater volume of brain tissue may be associated with higher level of intellectual functioning. It is not clear, however, how to reconcile such findings with reports that individuals with profound developmental disorders, such as autism, have larger brains than appropriate control subjects (Piven *et al.*, 1996). Other investigations have focused more on regional microscopic anatomy in brains of gifted individuals in attempts to account for possible relationships between brain structure and mental skills (Bentivoglio, 1998; Witelson *et al.*, 1999).

The volumes of individual lobes and other subdivisions of the brain are generally highly correlated with overall brain size. One notable exception to this rule is the occipital lobe. This may be because the occipital lobe is one of the regions of the brain that shows the greatest individual variability in both men and women. When adjusting for overall brain volume, there is a negative correlation between the frontal lobe and parietal lobe volume, which has been interpreted by some to suggest that the evolutionary expansion of the frontal lobes in humans may have come at the expense of a reduction in parietal lobe volume.

The volume of the lateral ventricles is highly variable, and in general is not associated with overall brain size. Attempts to correlate variability in the size of various brain regions with specific cognitive profiles, such as reading disability, have met with only variable degrees of success (Pennington *et al.*, 1999).

Gyral Patterns and Regional Variability

The most striking individual differences in the gross morphology of the human brain are in the patterns of gyri and sulci. Although the subject of multiple investigations, the behavioral significance of this variability remains unknown (Whitaker and Selnes, 1976). There is some, although not complete, correspondence between the gyral pattern and the boundaries of cytoarchitectonic fields. While the greatest degree of individual differences is observed for the minor sulci and gyri, there is also considerable interindividual variability in the configuration of the Rolandic and Sylvian fissures. The gyral patterns of the cingulate region are likewise subject to a wide range of configurations (Paus *et al.*, 1996; Ide *et al.*, 1999).

The variability in configuration and size of specific brain regions involved in language was pointed out by early anatomists such as Constatin von Economo (1876–1931). For example, the planum temporale, which is located adjacent to the primary auditory cortex on the posterior portion of the supratemporal plane, shows particularly striking variability across individuals. The potential functional significance of such variability can best be evaluated in the context of the overall variability of the brain. There is considerable evidence that brain regions not related to language, such as the striate cortex, show a similar, if not greater, degree of variability.

White Matter Tracts

Considerable individual variability has been reported in the size of the corpus callosum, apparently related, at least in part, to variability in overall brain volume. There is no consensus regarding the relationship between callosal size and handedness. On the assumption that a larger volume of the corpus callosum may relate to improved interhemispheric integration, some studies have attempted to correlate overall callosum size with overall intellectual performance. A modest correlation between performance on some neuropsychological tests and callosal size has been found for women, but not for men (Davatzikos and Resnick, 1998). Interpretation of these findings is somewhat unclear because other investigators have reported a larger volume of the corpus callosum in dyslexic adults than in age-matched controls (Robichon and Habib, 1998). The results of studies attempting to correlate corpus callosum volume to measures of cerebral laterality, such as dichotic listening, have yielded somewhat conflicting results. There is some evidence, however, suggesting that a greater degree of asymmetry of perisylvian language regions is associated with a smaller volume of the corpus callosum. This may imply that as the degree of asymmetry between the two hemispheres has evolved, the degree of interhemispheric connectivity has gradually reduced. The development of the myelin of the corpus callosum is not complete until after age 10 years, which appears to coincide with the so-called critical period for language development. After this period, acquisition of phonological skills with a degree of competence comparable to that of a native speaker is no longer possible. Developmental studies have shown that the volume of the corpus callosum continues to increase until the middle of the second decade of life (Pujol *et al.*, 1993). The high prevalence of bilateral language representation in individuals who are born without a corpus callosum has suggested to

some that it may play a role in the development of unilateral language representation (Selnes, 1974).

Brain Asymmetries

The possibility of identifying regional brain structural correlates of language dominance was first introduced by the studies of Geschwind and Levitsky (Geschwind and Levitsky, 1968). They reported that in a sample of 100 autopsy brains, the planum temporale, located behind Heschl's gyrus on the supratemporal plane of the temporal lobe, was approximately one-third larger in the left hemisphere. This discovery stimulated considerable interest in defining the degree and pattern of language-related interhemispheric asymmetries, and subsequent autopsy and volumetric MRI studies have confirmed that the planum temporale is larger in the left hemisphere of the brain in 65% to 95% of cases.

Anatomical asymmetries involving the lateral aspect of the frontal cortex, including the anterior speech regions, have also been reported. Volumetric MRI of the third inferior frontal gyrus (Broca's area), have shown that this region is larger in the left hemisphere for most individuals. Broca's area is made up of two distinct subregions, the pars triangularis and the pars opercularis. Whereas the pars triangularis shows a consistent leftward asymmetry regardless of handedness, the directionality of the asymmetry of the pars opercularis appears to be predicted by handedness. It is larger on the left in right-handers, but larger on the right in left-handers (Foundas *et al.*, 1998). Asymmetries at the microscopic level have also been demonstrated for both the posterior and anterior language areas (Amunts *et al.*, 1999).

The functional significance of the structural asymmetry of the brain regions involved in language remains unclear. Most early studies hypothesized that the larger left planum temporale was a 'marker' of the left hemisphere specialization for language functions. The close proximity of the planum temporale to brain regions involved in comprehension of language (Wernicke's area) supported this argument. There is no direct evidence, however, that the planum temporale plays a specific role in language comprehension (Binder *et al.*, 1996). Lesions restricted to this area do not appear to result in any linguistic deficits. There is also a mismatch between the approximate 65% prevalence of leftward anatomical asymmetry and the 95% prevalence of left hemisphere language dominance.

More recent studies have demonstrated that cortical asymmetries may be present even in the absence of any known asymmetry or lateralization at the functional level. Moreover, it has become increasingly clear that regional hemispheric asymmetries can best be interpreted in the context of overall hemisphere asymmetries. The overall volume of the right hemisphere is greater than that of the left, suggesting that, for most individuals, there is more brain tissue in the right than left hemisphere.

The right hemisphere on average extends further anteriorly, while the left hemisphere extends further posteriorly. Asymmetries involving the volume of white matter in the two hemispheres have also been described. For the frontal and temporal lobes, the volume of white matter is greater in the left hemisphere than the right (Pujol *et al.*, 2002).

Subcortical Asymmetries

The roles of subcortical structures in speech and language functions have long been somewhat controversial. Current data suggest that subcortical lesions may influence the function of cortical regions through mechanisms of hypoperfusion (Hillis *et al.*, 2004). Anatomical asymmetries at the subcortical level have been reported for the caudate nucleus, which shows a consistent right-greater-than-left volume. The volume of the insular cortex, which has been implicated in language functions, also shows an asymmetry in favor of the right being larger than the left (Watkins *et al.*, 2001).

Although the hippocampus is not traditionally thought of as being part of the human language system, verbal memory is nonetheless an integral part of language. The vast majority of studies that have reported on asymmetries in the volume of the hippocampus have concluded that the right is larger than the left. This is perhaps somewhat surprising since we traditionally think of verbal memories as being more highly developed than visual memory systems.

White Matter Tract Asymmetries

Recent imaging techniques such as diffusion tensor imaging (DTI) allow more detailed quantification of specific white tracts of the brain. One recent study found an asymmetry of the arcuate fasciculus favoring the left hemisphere (Buchel *et al.*, 2004). The arcuate fasciculus has long been thought to be involved in language functions, specifically in the ability to repeat auditory information. A lesion of the arcuate fasciculus was once believed to be the principal mechanism underlying the syndrome of conduction aphasia. However, more recent studies have questioned the role of the arcuate fasciculus in repetition (Selnes *et al.*, 2002), and the significance of a more prominent left-hemisphere arcuate fasciculus is therefore unclear.

Asymmetry in Nonhumans

Although it was originally believed that the asymmetries of the temporal lobe regions involved in language were unique to man and not present in the great apes, more recent studies suggest that this may not be the case. Interpretation of these newer findings has been the subject of considerable debate, however. In the case of humans, the distribution of the asymmetry of the planum temporale involves approximately 65% with greater left than right, symmetry in 24%, and a larger volume on the right in 11%. In one series of great apes, 17 out of 18 were found to have a larger left than right planum temporale (Gannon *et al.*, 1998). This has led some to suggest that the volume and degree of this particular region of the brain may not be directly related to the human capacity for language.

Conclusions

Considerable individual variability has been documented for both the macro- and microscopic anatomy of the brain. Asymmetries between the two hemispheres, with some favoring the left hemisphere, are also well documented. The functional significance of asymmetries involving language areas remains unknown. In many cases, regional variability is greater than that of interhemispheric asymmetries. While larger volumes of brain tissue have often been equated with greater functional propensities, the evidence for this remains controversial. Asymmetries at the gross morphological level can reflect differences in underlying neuronal or glial density, white matter tracts, or other components, and it is not known how each of these factors may contribute to the brain's overall cognitive capacity.

Anatomical Nomenclature: History

A History of Anatomical Nomenclature

The origins of anatomy, the systematic study and description of the structure of the body, lie submerged in remote antiquity. Like other branches of ancient learning, anatomy had both a practical side, serving the needs of physicians, surgeons, augurs, and embalmers, and a purely speculative one of seeking knowledge for its own sake.

Anatomy underlies much of the study and practice of medicine, surgery, dentistry, and nursing. Gross anatomy deals with the form, location, and relations of body parts, external and internal, that are visible to the naked eye. Collateral disciplines include histology, which is the microscopic study of cells and tissues, and embryology, which traces the development of the body from a fertilized oocyte. In addition to its role in the health sciences, anatomy supplies critical data for the design of clothing, furniture, passenger vehicles, tools, and living and working spaces and supports the graphic and plastic arts.

If science consists in the collection and classification of data, the formulation of hypotheses, the performance of experiments to test those hypotheses, and the establishment of general principles or laws, then anatomy barely makes the grade as a science. Its purely descriptive character has strongly influenced the development of its technical language. In such a field of inquiry, a precise and orderly system of nomenclature is of critical importance.

Just as the history of a culture becomes imbedded and memorialized in its language, the history of an art, craft, or scientific discipline lives in its technical nomenclature or jargon. In addition to creating new terms as needed, anatomists at each succeeding stage in the development of the science have retained and adapted terms inherited from their predecessors.

This article surveys the evolution of anatomical nomenclature against the background of the history of human anatomy in Western science, beginning with unsystematic lay terminology and ending with modern international codifications. With this focus, the emphasis must be on terms derived from Greek and Latin, but the parallel development of anatomical nomenclature in English will also be noted.

Classical Period (800 B.C.–200 A.D.)

Greek

The earliest anatomical lore was crude, inaccurate, disorganized, and limited by its goals and uses, whether butchering animals, treating the wounded, or embalming the dead. When Homer (9th century B.C.) composed his epics, there was no scientific discipline of anatomy and hence no anatomical nomenclature as distinct from the general vocabulary. If we begin our study at so early a date, it is because even in the *Iliad* and the *Odyssey* we find terms that survive to this day in the standard language of Western anatomy and medicine, at least as stems for adjectives or as combining forms incorporated into compound words.

In homeric words such as *brakhiōn* 'arm', *derma* 'skin', *haima* 'blood', *ophthalmos* 'eye', *osteon* 'bone', *pneumōn* 'lung', and *sōma* 'body' the reader will recognize components of modern biomedical language. The precision of a nomenclatural system seldom exceeds that of the fund of knowledge that it supports and illuminates. The freedom with which Homer uses some anatomical words has its close parallel in modern colloquial English. Thus, *gastēr* can mean 'stomach' as the organ of digestion, 'abdomen' in general, or even 'uterus, womb'. Like his contemporaries, Homer made no distinction between arteries and veins, using the word *phleps* for both.

As early as Homer, the collarbone had acquired the figurative name *kleis* 'key'. In modern medical terminology, the Greek word survives only as a combining form (*cleidocostal, cleidotomy*). Meanwhile, a Latin version, *clavicula* 'little key' (English *clavicle*), has replaced the Greek noun. The history of this word

A History of Anatomical Nomenclature

The origins of anatomy, the systematic study and description of the structure of the body, lie submerged in remote antiquity. Like other branches of ancient learning, anatomy had both a practical side, serving the needs of physicians, surgeons, augurs, and embalmers, and a purely speculative one of seeking knowledge for its own sake.

Anatomy underlies much of the study and practice of medicine, surgery, dentistry, and nursing. Gross anatomy deals with the form, location, and relations of body parts, external and internal, that are visible to the naked eye. Collateral disciplines include histology, which is the microscopic study of cells and tissues, and embryology, which traces the development of the body from a fertilized oocyte. In addition to its role in the health sciences, anatomy supplies critical data for the design of clothing, furniture, passenger vehicles, tools, and living and working spaces and supports the graphic and plastic arts.

If science consists in the collection and classification of data, the formulation of hypotheses, the performance of experiments to test those hypotheses, and the establishment of general principles or laws, then anatomy barely makes the grade as a science. Its purely descriptive character has strongly influenced the development of its technical language. In such a field of inquiry, a precise and orderly system of nomenclature is of critical importance.

Just as the history of a culture becomes imbedded and memorialized in its language, the history of an art, craft, or scientific discipline lives in its technical nomenclature or jargon. In addition to creating new terms as needed, anatomists at each succeeding stage in the development of the science have retained and adapted terms inherited from their predecessors.

This article surveys the evolution of anatomical nomenclature against the background of the history of human anatomy in Western science, beginning with unsystematic lay terminology and ending with modern international codifications. With this focus, the emphasis must be on terms derived from Greek and Latin, but the parallel development of anatomical nomenclature in English will also be noted.

Classical Period (800 B.C.–200 A.D.)

Greek

The earliest anatomical lore was crude, inaccurate, disorganized, and limited by its goals and uses, whether butchering animals, treating the wounded, or embalming the dead. When Homer (9th century B.C.) composed his epics, there was no scientific discipline of anatomy and hence no anatomical nomenclature as distinct from the general vocabulary. If we begin our study at so early a date, it is because even in the *Iliad* and the *Odyssey* we find terms that survive to this day in the standard language of Western anatomy and medicine, at least as stems for adjectives or as combining forms incorporated into compound words.

In homeric words such as *brakhiōn* 'arm', *derma* 'skin', *haima* 'blood', *ophthalmos* 'eye', *osteon* 'bone', *pneumōn* 'lung', and *sōma* 'body' the reader will recognize components of modern biomedical language. The precision of a nomenclatural system seldom exceeds that of the fund of knowledge that it supports and illuminates. The freedom with which Homer uses some anatomical words has its close parallel in modern colloquial English. Thus, *gastēr* can mean 'stomach' as the organ of digestion, 'abdomen' in general, or even 'uterus, womb'. Like his contemporaries, Homer made no distinction between arteries and veins, using the word *phleps* for both.

As early as Homer, the collarbone had acquired the figurative name *kleis* 'key'. In modern medical terminology, the Greek word survives only as a combining form (*cleidocostal, cleidotomy*). Meanwhile, a Latin version, *clavicula* 'little key' (English *clavicle*), has replaced the Greek noun. The history of this word

foreshadows the evolution of many other anatomical terms in current use, by its origin in a Greek metaphor, its eventual replacement with a translation into Latin, and the use of a diminutive suffix to form the Latin term.

Honored as the Father of Medicine because he was the first Western medical authority to distinguish clearly between medicine and religion, Hippocrates (460–370 B.C.) asserted that diseases have physical causes, stressed the importance of observation in diagnosis, and relied strongly on diet, exercise, and the healing powers of nature.

The writings that make up the voluminous hippocratic corpus cannot all be the work of one man. Differing in language, style, and viewpoint, they represent an ancient medical library, whose preservation through 25 centuries is little short of miraculous. If most of the hippocratic writings, even including the celebrated *Oath*, were probably not composed by the Hippocrates of history, most of them at least represent the teachings and traditions of his school.

Hippocrates was a physician, not an anatomist. In *On the sacred disease*, he reports having dissected the brains of goats, but it is virtually certain that he did not practice human dissection. His knowledge of anatomy is uneven, sometimes garbled by the humoral physiology that he borrowed and adapted from Empedocles.

According to that system, everything in the physical universe can be reduced to four elements: earth, air, fire, and water. The properties of material substances depend on their relative proportion of heat and cold, dryness and wetness. Translated to the realm of physiology, this cosmologic system yielded a rigidly foursquare scheme according to which health depends on a due balance among four humors: blood, phlegm, yellow bile, and black bile (the last a pure invention).

Hippocrates sometimes distinguished veins (*phlebes*) from arteries (*artēriai*) but believed, like most of his contemporaries, that arteries contained or transported air rather than blood. The very word *artēria* (in the Ionic dialect used by Hippocrates and later medical writers, *artēriē*) means 'air passage', and in some of the hippocratic writings it refers specifically to the trachea or bronchi. In fact, our word *trachea* derives from the Greek phrase, later than Hippocrates, *artēria trakheia* 'rough air passage' (rough because, unlike true blood vessels, it is reinforced by incomplete rings of cartilage).

In Hippocrates, *neuron* can mean either 'tendon' or 'nerve', and what we know as the urethra he calls indifferently either *ourētēr* or *ourēthrē*. The use of *mus* 'mouse' to refer to a muscle, although unknown to Homer, had become standard by Hippocrates's time. This is another Greek anatomical noun based on a figure of speech that was eventually replaced in anatomical terminology by a Latin translation (*musculus*) incorporating a diminutive suffix.

In his surgical and orthopedic works, Hippocrates, like some other early medical writers, displays an exact knowledge of the human skeleton. The bones being the least perishable parts of the body, a full set of them might be acquired and thoroughly studied at leisure with no need to dissect a corpse. Hippocrates refers to the larger extremity of a bone as its *head* (*kephalē*), a usage that continues to this day. But he neither inherited a complete anatomical nomenclature from his forebears nor attempted to invent one. Thus, he has no specific terms by which to distinguish the bones of the forearm (radius and ulna) or those of the leg (tibia and fibula).

Many hippocratic terms illustrate the freedom with which classical Greek formed compound words by joining two or more stems. Thus, *akrōmia* (modern *acromion*), referring to the topmost part of the shoulder, is a fusion of *akros* 'highest' and *ōmos* 'shoulder'. In *haimorrhoides phlebes* 'hemorrhoidal veins' (from *haima* 'blood' and *rheō* 'to flow'), we have an anatomical term based on a disease or abnormal condition to which the parts named are subject.

Dozens of other hippocratic words survive, including *epidermis, epiphusis* 'epiphysis, bony process', *kanthos* 'canthus, corner of the eye', *karpos* 'carpus, wrist', *kondulos* 'condyle, bony knob', *kubiton* 'cubitum, elbow', *kustis* 'cyst, bladder', *masētēr* 'masseter, muscle of mastication', *meninges*, *peritonaion* 'peritoneum, lining membrane of the abdominal cavity', and *zugōma* 'zygoma, cheekbone'. Some have undergone marked changes of sense. Hippocrates's *brogkhos* is what we call the *trachea*, whose branches we call *bronchi*. His *stomachos* is our *esophagus*, which conducts swallowed materials into what we call the *stomach*.

During the generations that followed Hippocrates, the gradual development of anatomy as a systematic science demanded a specialized lexicon including words for numerous body structures not known to the generality of mankind.

Aristotle (384–322 B.C.), perhaps the most fertile and versatile intellect of antiquity, was certainly the most exact observer and perspicuous biological writer whose works have come down to us from before our era. Taking all nature as his province, he dissected numerous animals and founded the sciences of embryology and comparative anatomy. He was the first to refer to scientific dissection as *anatomē* 'cutting up'. His writings also contain the earliest use of the term *aorta* (*aortē*). Not Aristotle's coinages, but

unknown to Hippocrates, are *epiglōttis*, still the name for the membranous flap that closes the respiratory tract during swallowing, from *epi* 'on' + *glōtta* 'tongue', and *ōlekranon* (more properly *ōlenokranon*) 'olecranon, point of the elbow', from *ōlenē* 'elbow' + *kranon* 'hard place'.

We have only indirect records of the work of the Alexandrian physician Herophilus of Chalcedon (ca. 300 B.C.), the earliest known practitioner of human dissection, to whom we are indebted for such terms as *prostate* [Greek *adenoeideis prostatai* 'glandlike structures standing before (the outlet of the bladder)'] and *duodenum* [Latin '12-fold', based on Herophilus's *enteron dōdekadaktulon* '12-inch (part of the) bowel'].

Latin

The Romans of the late Republic and early Empire borrowed their science and philosophy wholesale from the Greeks. Most of the physicians in imperial Rome were Greek immigrants, slaves, or freedmen.

The Grecian provenance of Roman medical lore accounts for the presence in medical Latin of many Greek anatomical terms, some of them simply transliterated (*colon, thorax, meninges*), others equipped with Latin inflectional endings (*bronchus, cranium, stomachus*), and still others translated by obvious Latin cognates: *pulmo* 'lung', *tendo* 'tendon', and *trochlea* 'pulley', akin respectively to Greek *pleumōn, tenōn*, and *trokhilia*.

The Latin *vena cava* is a verbatim rendering of Hippocrates's *koilē phleps* 'hollow vein'. Terms for various parts of the intestine are also Latin versions of Greek terms, *jejunum, caecum*, and *rectum*, translating respectively the hippocratic *nēstis* 'starved, fasting' and the aristotelian *tuphlon* 'blind', and *euthu* 'straight'.

When the Latin poets of the Augustan age (Virgil, Horace, and Ovid) used terms such as *bilis* 'bile', *jecur* 'liver', *pituita* 'phlegm', and *stomachus* 'stomach', they were usually referring, more or less in earnest, to the doctrine according to which emotions such as anger, courage, and sexual passion depend on the relative preponderance of the humors.

Although the names applied by these writers and their contemporaries to other parts of the body were not components of a formal or specialized nomenclature but only of the vernacular, many of them later became essential elements of anatomical terminology and survive today in that setting: *cerebrum* 'brain', *dens* 'tooth', *femur* 'thigh', *gingiva* 'gum', *inguen* 'groin', *labium* 'lip', *lingua* 'tongue', *lumbus* 'loin', *medulla* 'marrow', *naris* 'nostril', *pectus* 'chest', *talus* 'heel, ankle', *unguis* 'nail', *vesica* 'bladder'.

The most valuable record of Roman anatomical language in the first century of our era is the work of Aulus Cornelius Celsus, who wrote during the reign of Tiberius (14–37 A.D.). Not a medical practitioner himself, Celsus composed encyclopedic treatises on various topics, but only his *De Medicina* has survived in a single incomplete manuscript. Even that was lost for centuries until Pope Nicholas V discovered it in the Vatican library in approximately 1450.

Celsus' vocabulary includes familiar anatomical Latin words such as *abdomen, anus, humerus, occiput, patella, radius, scrotum, tibia, uterus*, and *vertebra*. For structures without Latin names, he used Greek: *diaphragma*, *karōtidēs* (*carotid*), *kremastēr* (*cremaster*), *parōtis* (*parotid*), and *pyloros* (*pylorus*).

Greco-Roman

Even with the spread of Roman sociopolitical dominance, Greek words and word elements continued to make up a significant part of Western scientific terminology, as they still do today. The Greek-speaking physician Rufus of Ephesus, who practiced in Rome during the reign of Trajan (98–117 A.D.), compiled the first book of anatomical nomenclature, *On the naming of the parts of the body*. Only fragments of that work have come down to us. The suffix *-oeidēs* (English *-oid*) 'having the form of, resembling', was already productive at the time of Hippocrates. Among anatomical adjectives noted by Rufus are *arakhnoeidēs* 'like a spider web' (*arachnoid*), *hualoeidēs* 'glassy' (*hyaloid*), *keratoeidēs* 'horny' (later, Latin *cornea*), *khoroeidēs* 'like a placenta' (*choroid*), and *lambdoeidēs* 'like the letter lambda (Λ)' (*lambdoid*).

Some of Rufus' material is preserved in a later and more general dictionary–thesaurus, the *Onomasticon* of Julius Pollux (134–192 A.D.), which itself survives only in incomplete abridgments dating from the 9th century. Anatomical terms recorded by Pollux from his era include such modern survivors as *amnion* 'little lamb'; *atlas* 'god who supports pillars of universe', hence 'first cervical vertebra, which supports the skull'; *kleitoris* (*clitoris*); *tragos* 'goat; tragus, the hairy tab in front of the opening of the ear'; and *trochantēr* 'running apparatus', referring to either of two processes near the upper end of the thigh bone, to which muscles are attached.

In the brilliant work and voluminous writings of the Greco-Roman physician Galen (Claudius Galenus, 129–199 A.D.), classical medicine reached both a pinnacle and a dead end. A native of Pergamum in Asia Minor, Galen studied medicine with Greek teachers

but spent much of his professional life in Rome, where he lived during the reigns of Hadrian, the Antonines, Commodus, and Severus.

The interval between Hippocrates and Galen was more than 500 years, half again as long as that which separates us from William Harvey (1578–1657), the discoverer of the circulation of the blood. Although he revered Hippocrates as a supreme authority, Galen did much original and painstaking research. He showed that arteries as well as veins carry blood. His anatomy, particularly his description of the brain, muscles, and nerves, is detailed and accurate, although he sometimes arrived at wrong conclusions by dissecting apes rather than human subjects.

Galen's comprehensive, articulate, and practical medical writings held sway in the Western world for approximately 1500 years. Anatomical terms used by Galen that survive in modern use include *allantois, anastomosis, aponeurosis, azygos, epididymis, iris, pancreas, psoas*, and *symphysis*.

Middle Period (200–1700 A.D.)

The social upheaval, moral collapse, and political fragmentation of the Roman empire that followed the earliest centuries of the Christian era led inevitably to a decline in science and scholarship. During the period we call the Dark Ages, the rich heritage of Greek culture and science gradually faded, to be replaced by an artificial and distorted facsimile. A rigid dogmatism stifled the spirit of inquiry and creative research by exalting the ancient authorities Aristotle, Hippocrates, and Galen, who were often known only through inaccurate Latin translations, abridgments, and commentaries.

While spoken Latin slowly evolved and differentiated into the Romance languages and dialects, the classical tongue survived as the universal medium of scholarship, jurisprudence, and Christian doctrine and worship. But even though anatomical and medical works were written in Latin, they contained many latinized forms of Greek words retained from antiquity.

Despite the general climate of intellectual torpor, a few original workers contributed to the gradual accretion of anatomical knowledge and also to an increasingly voluminous and unsystematic lexicon. Many of their terms survive and illustrate linguistic patterns that still largely determine the structure of anatomical nomenclature.

A purely descriptive term might be based on the shape of an anatomical feature (*ligamentum teres* 'round ligament', *musculus rectus* 'straight muscle'), its size (*foramen magnum* 'large aperture', *musculus longissimus cervicis* 'longest muscle of the neck'), its position (*arteria subclavia* 'artery beneath the clavicle', *vena circumflexa femoris lateralis* 'vein winding around the outer side of the thigh'), its shape or course (*musculus biceps* 'two-headed muscle', *nervus vagus* 'wandering nerve'), or its function (*adductor hallucis* 'adductor of the thumb', *levator scapulae* 'elevator of the shoulder blade').

Latin descriptive adjectives containing the suffix *-formis* 'in the form of, resembling' followed the model of Greek terms in *-oeidēs*, sometimes latinized as *-oideus*. Surviving English derivatives of these terms include *cuneiform* 'like a wedge', *falciform* 'like a sickle', and *pampiniform* 'like a tendril'.

A few frank metaphors have already been noted among early Greek anatomical terms. Further examples are *amygdala* 'almond' for 'tonsil', *gastroknemiē* 'gastrocnemius, belly (i.e., calf) of the leg' (a hippocratic word), *khitōn* 'tunic' for 'layer of a structure', *kokkuks* 'cuckoo' for 'tailbone, coccyx', and *lēnos* 'winepress', denoting the confluence of venous sinuses at the rear of the cranial cavity.

In anatomical Latin, metaphor proved to be a far more fertile process. A structure might be named after another body part (*crus* 'leg', *genu* 'knee', *os* 'mouth'), often with a diminutive suffix (*auricula* 'little ear', *capitellum* 'little head', *ventriculus* 'little belly'); an animal (*cochlea* 'snail', *hippocampus* 'seahorse', *vermis* 'worm') or animal part (*ala* 'wing', *cornu* 'horn', *cauda* 'tail'); a plant or plant part (*arbor* 'tree', *glans* 'acorn' and *glandula* 'little acorn', *ramus* 'branch'); a topographic feature (*crista* 'ridge', *fovea* 'pit', *fossa* 'ditch'); a man-made structure (*atrium* 'forecourt', *pons* 'bridge', *tectum* 'roof'); a household article (*acetabulum* 'vinegar bowl', *infundibulum* 'funnel', *pulvinar* 'pillow'); or a tool or other familiar object (*fibula*, 'brooch', *malleus* 'hammer' and *malleolus* 'little hammer', *vomer* 'plowshare').

Medieval anatomists borrowed from contemporary Latin some words that had been unknown in classical times, such as *cerumen* 'earwax', *stapes* 'stirrup', and *soleus* 'pertaining to the sole of the foot' (from *solea* 'sandal', from *solum* 'the ground').

In some patterns of word formation, we can see the results of early efforts at systematization. Aristotle applied the term *mesenterion* to the membrane that anchors the intestine to the body wall and through which it receives its blood supply, a structure known to this day by the English word *mesentery*. Mondino of Luzzi (1275–1326) called it by the latinized form *mesenterium*. That term has spawned a numerous progeny, all based on the analogic sense of *meso-* as 'supporting or anchoring membrane'. Words in this family formed with Greek stems include *mesometrium* (from *mētra* 'uterus') and *mesorchium* (*orkhis*

'testicle'), and, without suffix, *mesocolon* and *mesosalpinx* (*salpigks* 'uterine tube'); from Latin, *mesopulmonum* (*pulmo* 'lung') and *mesotendineum* (*tendo* 'tendon'), and, without suffix, *mesoappendix* and *mesoduodenum*; from English, *mesocord* and *mesosigmoid*.

Several instances of the Greek practice of joining the stems of two nouns to form a third have already been noted. Unlike Greek, Latin preferred to name composite ideas with phrases. As advancing knowledge permitted finer discrimination among similar entities, anatomical nomenclature evolved almost inevitably into a taxonomy or classification. Many structures thus came to be designated by phrases on the pattern of genus + species: *cornu majus* 'larger horn', *cornu minus* 'smaller horn'; *ventriculus dexter* 'right ventricle', *ventriculus sinister* 'left ventricle'.

Pursuing another natural line of development, anatomical language employed a hierarchical system of naming to reflect the repeated branching of structures, such as blood vessels and nerves. The following partial tabulation of the branches of the external carotid artery, containing English terms in use during the 19th century, illustrates some of the features of such a scheme (Table 1).

Table 1 Branches of the external carotid artery

External carotid artery	
Superior thyroid artery	
	Hyoid branch
	Superficial descending branch
	Superior laryngeal branch
	Cricothyroid branch
Lingual artery	
	Hyoid branch
	Dorsal branch
	Sublingual branch
	Ranine branch
Facial artery	
Cervical division	
	Inferior branch
	Tonsillar branch
	Submaxillary branch
	Submeatal branch
	Muscular branches
Facial division	
	Muscular branches
	Inferior labial branch
	Inferior coronary branch
	Superior coronary branch
	Lateral nasal branch
	Angular branch
Occipital artery	
	Muscular branches
	Sternomastoid branch
	Mastoid branch
	Auricular branch
	Meningeal branch
Posterior auricular artery	
	Stylomastoid branch
	Auricular branch
	Mastoid branch
Ascending pharyngeal artery	Prevertebral branches
	Tympanic branch
	Meningeal branch
Superficial temporal artery	
	Transverse facial branch
	Middle temporal branch
	Anterior auricular branch. . . etc.

Note that whereas *lingual artery* and *posterior auricular artery* are unique designations, each of the descriptive adjectives in italics is used more than once to name branches. Although this recycling of a basic vocabulary of qualifying words contributes in a way to the overall economy of the system, it also requires the use of cumbersome phrases to distinguish, for example, the *hyoid branch of the superior thyroid artery* from the *hyoid branch of the lingual artery*, and the *muscular branch of the cervical portion of the facial artery to the stylohyoid muscle* from the *muscular branch of the facial portion of the facial artery to the stylohyoid muscle*.

Additional evidence of increasing systematization appears in the emergence of Latin compound adjectives in which the linkage of two terms (often with coupling *o*) signifies a physical relationship. Thus, *ligamentum calcaneonaviculare*, 'ligament joining the calcaneal and navicular bones', *musculus coracobrachialis* 'muscle between the coracoid process of the scapula and the bone of the arm', and *valva ileocaecalis* 'valve between the ileum and the cecum'.

In the absence of any central or unifying authority, the language of anatomy grew increasingly cluttered with synonyms referring to the same body parts and with terms that meant one thing to one writer and something else to another. One source of confusion was the parallel use of Greek and Latin words for the same structures. Modern anatomical language still reflects some of this duplication. Thus, we have *dermal* and *cutaneous*, 'pertaining to the skin'; *ethmoid* and *cribriform*, 'sievelike'; *peroneal* and *fibular*, 'pertaining to the fibula'; *scaphoid* and *navicular*, 'boatlike'; *sphenoid* and *cuneiform*, 'wedge-shaped'; *xiphoid* and *ensiform*, 'swordlike'.

The spelling of some terms became permanently distorted through confusion between similar, often cognate, words in the two languages. Many instances of such confusion arose from mishandling of the Greek letter upsilon (*Y*, which in this article is consistently transliterated by Roman *u*). Pronounced in classical times like modern French *u* and German *ü*, but never like the Latin *u*, *Y* was borrowed by speakers of Latin to spell Greek loan-words in which it occurred.

Under the influence of Greek *dakruma* 'tear', the cognate Latin word *lacrima* was re-spelled *lacryma* and even *lachryma*. *Lympha* 'pure water' is a fusion of Greek *numphē* 'water sprite', hence 'water', with Latin *limpida* 'clear, limpid'. Latin *piriformis* 'pear-shaped' (from *pirum* 'pear') was re-spelled *pyriformis* through confusion with Greek *pur* 'fire', and the mistake survives in English *pyriform*. Greek *stulos* 'pillar, post' caused Latin *stilus* 'pointed stake, writing implement' to be rewritten *stylus*, thus eventually determining the spelling of English *style* 'manner of writing'. In each case, the phonetic and orthographic blending was favored by a similarity of meaning (for example, pears and flames are roughly similar in shape).

Although medieval Arabian physicians did little original research – human dissection being forbidden by Islam – they performed an invaluable service to Western medicine by preserving and disseminating Greek medical works in Arabic versions. As these writings were further translated into Latin, words of Arabic origin, such as *alcohol, alkali, antimony, camphor, elixir, sugar*, and *syrup*, became a permanent part of the Western scientific vocabulary.

The anatomical term for the nape of the neck, *nucha*, comes from Arabic *nuḫḫ* 'marrow', and the saphenous veins are so called from their Arabic name, *sāfin*. *Dura mater* and *pia mater*, anatomical Latin terms for the membranes (meninges) covering the brain and spinal cord, mean literally 'tough mother' and 'gentle mother'. These are calques based respectively on Arabic *'umm ad-dimāḡ assāfigah* and *'umm raqīqah*, which might be more aptly translated 'thick envelope' and 'thin envelope'.

Dissection of the dead for anatomical study was first permitted by secular authorities in Italy early in the 14th century. During the following decades, scores of meticulous workers across Europe advanced the science of anatomy by discovering or rediscovering parts of the body and refining the understanding of their structure and relations. The names of many of these pioneering anatomists became attached to parts they had described. Although Rufus, Galen, and others had observed the uterine tubes, they came to be called *fallopian* after Gabriele Falloppio (1523–1562), who wrote the first complete and accurate description of them. His contemporary, Bartolommeo Eustachio (1524–1574), is honored for his rediscovery of the pressure-regulating passages (eustachian or pharyngotympanic tubes) leading from the middle ears to the throat, which had been described by Alcmaeon and Aristotle 2000 years earlier.

By the middle of the 15th century, printed broadsheets and books containing descriptions and woodcuts of human anatomy had begun to appear. Andreas Vesalius (1514–1564), a Flemish-born professor of anatomy at Padua, was among the first to practice human dissection extensively. His great work, *On the structure of the human body* (1543), was a milestone in the history of the science not only for its detailed, exact, and artistic illustrations but because it corrected many of the errors of his predecessors, particularly Galen.

In addition to expanding and improving the science of anatomy, Vesalius sought to reform its nomenclature, purging it of superfluous synonyms and of Greek, Arabic, and post-classical Latin words. Thus, he opted for Latin *auriculae cordis* 'auricles of the heart' instead of Greek *kardias ōta*, *os sacrum* 'holy bone' instead of *ieron osteon*, and *vena portae* 'portal vein' instead of *pulēs phleps*. But although these reforms have survived, others (*meatus urinarius* instead of *ureter*, *processus mammillaris* for *processus mastoideus*, and *rotator magnus* for *megas trochantēr*) have not.

From the 17th century onward, the proliferation of eponyms such as *the ampulla of Vater, Bartholin's glands, Hunter's canal, Poupart's ligament*, and *the sinus of Valsalva* further complicated an already vast and chaotic vocabulary. In addition, the invention of the microscope by Anton Leeuwenhoek (1632–1723) and its application to anatomy by Marcello Malpighi (1628–1694) and others set off an explosion of new information and created a need for hundreds of new terms.

Modern Period (1700 A.D.–Present)

Nowadays, as in the past, anatomical lore and its terminology serve chiefly as foundations for the study and practice of the healthcare professions. While modern anatomists probe ever more deeply, by means of the electron microscope and histochemical methods, into the fine structure and molecular function of cells and tissues, physicians, surgeons, nurses, and physical therapists deal chiefly with gross structures – bones, muscles, arteries, veins, nerves, and internal organs.

The nomenclature of gross anatomy, in addition to providing labels for those structures, also supplies a stock of combining forms with which to name abnormal conditions (*appendicitis, nephrolithiasis* 'stone formation in the kidney', *spondylolisthesis* 'slipping of a vertebra'), surgical procedures (*adenoidectomy, colostomy, laparoscopy*), and other medical entities and concepts.

Because little has been added to our fund of knowledge in gross anatomy since the 17th century, the nomenclature of the science has expanded only

slightly. But a persistent and increasing lack of pattern and uniformity has added to the burden of students who must not only learn the shapes, positions, and relations of thousands of structures but also memorize their names.

In 1886, when anatomists from several European countries met in Berlin to form an international Anatomical Society (*Anatomische Gesellschaft*), they gave high priority to the compilation of an international lexicon of anatomy that would eliminate many of the complexities and inconsistencies of the existing system and do away with semantically opaque eponyms. Their first convention was held the following year in Leipzig. From a corpus of some 50 000 Latin terms, they chose approximately 4500, which were published in 1895 in Basel, Switzerland, and became known as the *Basel Nomina Anatomica* (*BNA*).

The new system was gradually adopted in areas that were already using anatomical Latin – western Europe and the English-speaking countries. But *BNA* never won universal acceptance. Major revisions were approved at conventions in Birmingham (United Kingdom) in 1933 and (after reorganization of the society in the wake of World War II) in Paris in 1950.

Meanwhile, the International Federation of Associations of Anatomists (IFAA), founded in 1903, was also working toward the establishment of a uniform nomenclature for the anatomical sciences. This body made periodic revisions of *BNA*, but it was not until 1955, at the Sixth Federative International Congress of Anatomy in Paris, that a version was approved that went on to achieve nearly universal acceptance. This nomenclatural system, now known as *Nomina Anatomica* (*NA*), was officially revised in 1961, 1966, 1977, and 1983.

In 1989, the 13th Federative Congress of Anatomy appointed an international Federative Committee on Anatomical Terminology (FCAT) to undertake a thorough overhaul of *NA*. The result of their efforts, the most extensive revision of international nomenclature for human anatomy in several decades, was published as *Terminologia Anatomica* (*TA*) in 1997. Of its 7500 terms, approximately 1000 were new to official nomenclature, although many of them had long been in unofficial use. Approximately 10% of the terms that had appeared in the 6th revision of *NA* were either altered or rejected in *TA*.

Modern workaday anatomical language displays most of the quirks and irregularities that can be found in any living speech system. Outmoded terms, such as *auricles* for the cardiac atria, and eponymous ones, such as *fallopian tubes* for the uterine tubes, persist in speech and writing despite quasi-official efforts to expunge them. Terms long known to be based on erroneous beliefs are retained, partly because few now understand their etymology but chiefly because of the inconvenience of replacing them. Thus, we still refer to the superficial *cephalic veins* of the upper limbs as if we continued to believe that they drain blood directly from the head. The term *cardia* (Greek *kardia* 'heart') 'upper part of the stomach' reflects a primitive confusion between the two organs.

Other words and stems retain dual meanings despite occasional misunderstandings. Because Greek *muelos* 'pith, marrow' denotes both the spinal cord and the marrow of long bones, a *myelogram* is 'a radiographic image of the spinal cord', whereas *myelocyte* means 'a cell formed in bone marrow'. The adjective *tarsal*, from Greek *tarsos* 'wicker frame', refers to both the ankle joint and the connective tissue framework of the eyelid. *Cervical glands* can be either lymph glands in the neck or mucous glands of the uterine cervix.

For more than 1000 years, Latin served as the natural medium of anatomical discourse because, by an accident of history, it had become the international language of scholarly and technical communication. When Latin ceased to be spoken as a vernacular, it gained the additional appeal of no longer being subject to the phonetic, semantic, and orthographic instability of a living language.

But with shifts in educational objectives and methods, Latin began to drop out of the basic academic curriculum throughout most of the Western world approximately a century ago. Even before that time, words from national vernaculars had begun to replace Greek and Latin not only in speech but also in published works. As English gradually assumed the role of an international language in science and other fields, anatomical terms from that language gained international currency. Although *TA* is a strictly Latin vocabulary, it includes an English equivalent for each term.

Modern health professionals who speak English employ a mixture of classical and vernacular anatomical terms. Body parts that have familiar English names (*brain, eye, kidney, liver, wrist*) are commonly so designated. (Physicians do, however, occasionally resort to a Greek word such as *hepar* 'liver' or a Latin one such as *cor* 'heart' when discussing a grave prognosis in the presence of a patient.)

Often a structure is named with an English noun, whereas the corresponding adjective is based on a Latin stem, and related medical and surgical nouns are derived from Greek: *brain – cerebral – encephalogram, kidney – renal – nephrectomy, tongue – lingual – glossitis*. Many of the English terms in general use are anglicized Greek (*diaphragma* > *diaphragm*, *splēn* > *spleen*) or Latin (*ligamentum* > *ligament, ventriculus* > *ventricle*).

For other structures, it is usual to use Greek (*epiglottis, larynx, pancreas*) or Latin (*occiput, tibia, vertebra*), particularly when their names are single words. Latin is preferred for body parts that have no polite names in the vernacular (*anus, penis, vulva*). Some parts have current names in both languages: *astragalus/talus* 'ankle bone', *pharynx/fauces* 'throat'.

For structures with phrasal names in anatomical Latin, direct translations into English are usual: *arteria meningea media* > *middle meningeal artery, nervus ilioinguinalis* > *ilioinguinal nerve*. Often such a phrase is not only replaced, at least in speech, by an English translation, but is also further abridged by suppression of its noun: *musculus deltoideus* > *deltoid muscle* > 'the deltoid'; *os sphenoidale* > *sphenoid bone* > 'the sphenoid'. Latin phrases undergo other forms of shortening as well, as when *membrana mucosa* becomes simple *mucosa* and *tunica cornea* 'horny layer [of the eye]' becomes *cornea*. The phrase *os humeri* 'bone of the shoulder' has been replaced by simple *humerus, os femoris* 'bone of the thigh' by *femur*.

Classical Latin has undergone various orthographic, phonetic, and grammatical modifications and depredations on being put to the service of modern anatomy. American spelling eliminates certain diphthongs from Latin and latinized Greek, changing *caecum* to *cecum* and *oesophagus* to *esophagus*. The plural noun *praecordia* '[structures lying] before the heart' is now the singular *praecordium* (American *precordium*) and *calvaria* 'dome of the skull' has changed its gender to become *calvarium* (not accepted by purists). Variant spellings of Latin words (*annulus* versus *anulus*, *antebrachium* versus *antibrachium*) and of English words derived from classical ones (*disc* versus *disk, mamillary* versus *mammillary*) flourish to generate uncertainty and discord.

During the 19th century and much of the 20th century, linguistic purists vehemently opposed any mixture of Greek and Latin lexical elements in the same compound word. This unreasoning prejudice is now largely a thing of the past, not because pedants and cranks no longer abound but mainly because most of those belonging to the present generation cannot distinguish between Latin and Greek.

Few modern physicians have studied classical languages and almost none have acquired, much less retained, a working Latin vocabulary or a mastery of Latin accidence. Mistakes in sense, grammar, and pronunciation are therefore commonplace. The *portio vaginalis* 'vaginal portion' of the uterine cervix, so named in contradistinction to the *portio supravaginalis*, is commonly called simply 'the portio' by physicians who seem to think the word means 'porch' or 'portico'.

As in lay speech, the plurals of classical nouns are a fertile source of error. Those who mistake *biceps* and *triceps* for plural forms create illegitimate subtraction singulars, *bicep* and *tricep*. *Phalanx* and *meninx* are apt to be replaced by *phalange* and *meninge* (three syllables each), derived by back-formation from the plurals *phalanges* and *meninges*. The incorrect plurals *ducti* and *plexi* for the fourth-declension nouns *ductus* and *plexus* are frequently formed by analogy with more numerous second-declension nouns such as *musculus* (*musculi*) and *nervus* (*nervi*).

Those who miss the point of the genitive inflectional endings in *tensor fasciae latae* 'tightener of the broad fascia' pronounce it *tensor fascia lata*. Speakers often misplace syllable stresses, for example, saying *glúteus* instead of *glutéus* but *pharyngéus* instead of *pharýngeus*. The latinized Greek word *raphe* 'seam' is so often mispronounced as if it were French that the blunder was even enshrined in the 6th edition of *NA* with a wholly inappropriate acute accent: *raphé*.

Held together by broad patterns of analogy and regularity, modern anatomical nomenclature serves the needs of its users despite its complexities. Its evolution, paralleling the development of anatomy as a scientific discipline, has brought it increasingly closer to three of the ideal qualities of a scientific nomenclature – exhaustiveness, consistency, and economy. It remains to be seen how much longer a nomenclatural system based on Latin, a language increasingly foreign even to the educated, can continue to meet the fourth ideal – ease of intelligibility.

Anchieta, José de (1534–1597)

R Cavaliere, Universidade Federal Fluminense, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Father José de Anchieta, who is known as the Apostle of Brazil, was born in San Cristóbal de la Laguna, Canary Islands, on March 19, 1534. Anchieta studied in Coimbra starting in 1548; in 1551, he entered the Jesuit order in that city. In 1553, the young priest went to Brazil in order to join the catechism indoctrination and began to teach Latin at the Piratininga School. Considering that the mission of Catholic indoctrination could only be successful if the priests could talk with the natives in their language, Anchieta managed to learn by himself, the Tupi language spoken by the coastal population of the new land. The result was the handbook, *Art of grammar of the most spoken language in the Brazilian coast* (1595). This work became a useful manual for the other Jesuits learning Tupi; nowadays, it is historiographically considered the first linguistic paper written in Brazil. Although, according to the Brazilian philologist Augusto Magne, "its manuscript was being used as a handboolk of Tupi at least in 1556" (Magne, 1946: 4–5), Anchieta's grammar obtained permission for its first edition 40 years later, in 1595. The work is structured on the basis of the Latin grammar, as well as all Romantic vernacular grammars of that time, such as Antonio de Nebrijas's and Fernão de Oliveira's. Anchieta's goal was for students to learn Tupi in his grammar by using previous knowledge that they brought from their study of other grammars. In the literary field, the Jesuit priest devoted his time to writing poems, letters, and dramatic pieces, following the planning of Gil Vicente's 'autos.' This magnificent body of work was produced in Tupi, Portuguese, Spanish, and Latin. Due to his familiarity with the literary language, Anchieta established a new pedagogical order, using plays to educate the young natives. On June 9, 1597, José de Anchieta died in the city of Reritiba, today renamed Anchieta, in the state of Espírito Santo, Brazil.

Father José de Anchieta, who is known as the Apostle of Brazil, was born in San Cristóbal de la Laguna, Canary Islands, on March 19, 1534. Anchieta studied in Coimbra starting in 1548; in 1551, he entered the Jesuit order in that city. In 1553, the young priest went to Brazil in order to join the catechism indoctrination and began to teach Latin at the Piratininga School. Considering that the mission of Catholic indoctrination could only be successful if the priests could talk with the natives in their language, Anchieta managed to learn by himself, the Tupi language spoken by the coastal population of the new land. The result was the handbook, *Art of grammar of the most spoken language in the Brazilian coast* (1595). This work became a useful manual for the other Jesuits learning Tupi; nowadays, it is historiographically considered the first linguistic paper written in Brazil. Although, according to the Brazilian philologist Augusto Magne, "its manuscript was being used as a handboolk of Tupi at least in 1556" (Magne, 1946: 4–5), Anchieta's grammar obtained permission for its first edition 40 years later, in 1595. The work is structured on the basis of the Latin grammar, as well as all Romantic vernacular grammars of that time, such as Antonio de Nebrijas's and Fernão de Oliveira's. Anchieta's goal was for students to learn Tupi in his grammar by using previous knowledge that they brought from their study of other grammars. In the literary field, the Jesuit priest devoted his time to writing poems, letters, and dramatic pieces, following the planning of Gil Vicente's 'autos.' This magnificent body of work was produced in Tupi, Portuguese, Spanish, and Latin. Due to his familiarity with the literary language, Anchieta established a new pedagogical order, using plays to educate the young natives. On June 9, 1597, José de Anchieta died in the city of Reritiba, today renamed Anchieta, in the state of Espírito Santo, Brazil.

Ancient Egyptian and Coptic

J D Ray, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

The Ancient Egyptian language is first attested a little before 3000 B.C., when the earliest inscriptions in hieroglyphic make their appearance. Connected texts of some length are found from about 2700 B.C., and these develop into a considerable literature, which forms one of our major sources of information about the ancient Near East. The language survived the downfall of the Roman Empire and the transition to Christianity, and in its latest form, written in a modification of the Greek alphabet, it is known as Coptic. Coptic survived until well after 1000 A.D. Egyptian therefore has the longest attested history of any language, and this makes it uniquely important to linguistics. The language is a member of the Afro-Asiatic family (sometimes referred to as Hamito-Semitic), although its exact place within this family is disputed. Many of the related languages were not written down until modern times, and several 'missing links' may never have been recorded at all. Egyptian shares the preference of most of this family for triconsonantal roots, from which whole families of words may be formed, normally through variations on the internal vowels and the use of some affixes. It may be this feature that encouraged the Egyptians to omit the vowels from their writing system. The language recognizes two genders, conventionally termed masculine and feminine; neuter meanings are expressed in the early stages of the language by the feminine, later by the masculine. It is possible that case endings, similar to those in some Semitic languages, existed at a very early stage of Egyptian, but they are not written and soon fell away. Traces may remain in the so-called construct state, where a direct genitive relationship is expressed by two nouns apparently in apposition. Grammatical function is marked by strict word order. A dual number is recognized alongside singular and plural.

The Egyptian verb has unique features. A stative tense, known in Coptic as the qualitative, seems to be inherited from an early stage of Afro-Asiatic, and has cognates in Akkadian (Egyptian). This tense expresses the result of a verbal action, and is often best rendered by an adjective or an adverbial phrase: 'open, continuous, far away, already knowing,' or the like. The narrative tense system, on the other hand, is peculiar to Egyptian, and appears to consist of various verbal nouns with possessive suffixes for subject ('his hearing' developing into 'he hears'). Other forms include a possessive construction with parallels to modern perfects ('hearing to him' developing into 'he has heard'), and an infixed series which expresses past, present, and future contingency. There is also a set of so-called active participles, which are really epithets or nouns of agent ('a hearer'), and a sequence of relative tenses formed from passive participles ('his heard one' developing into 'the one which he heard'). Participles and relative forms show two aspects, perfective and imperfective, depending on whether the action is envisaged as completed or not; there are also traces of a prospective, which has future or subjunctive force. Aspect also features in the narrative tenses, where prospective and probably circumstantial forms also occur. The language is VSO in narrative contexts, but stative constructions take the form SV. A remarkable feature is that four uses of the English verb 'to be' – existential, predicative, identifying, and partaking of a quality – are rendered by distinct constructions. On the other hand, there is no verb 'to have,' which is conveyed by periphrases such as 'there is to me.' A welcome omission is comparative inflection of adjectives: 'she is better than I' is expressed simply as 'she is good against/in respect to/ me.'

This is the form taken by Egyptian in its classic period, Middle Egyptian, during the early second millennium B.C. This canonical stage was recognized by the Egyptians themselves, and was retained in formal inscriptions until the end of Pharaonic history. However, after about 1400 B.C., pressure from the spoken language, which was constantly changing, began increasingly to affect the written texts. The result is Late Egyptian, which took over many of the functions of its predecessor. Late Egyptian, which is the direct ancestor of Coptic, stands to Middle

The Ancient Egyptian language is first attested a little before 3000 B.C., when the earliest inscriptions in hieroglyphic make their appearance. Connected texts of some length are found from about 2700 B.C., and these develop into a considerable literature, which forms one of our major sources of information about the ancient Near East. The language survived the downfall of the Roman Empire and the transition to Christianity, and in its latest form, written in a modification of the Greek alphabet, it is known as Coptic. Coptic survived until well after 1000 A.D. Egyptian therefore has the longest attested history of any language, and this makes it uniquely important to linguistics. The language is a member of the Afro-Asiatic family (sometimes referred to as Hamito-Semitic), although its exact place within this family is disputed. Many of the related languages were not written down until modern times, and several 'missing links' may never have been recorded at all. Egyptian shares the preference of most of this family for triconsonantal roots, from which whole families of words may be formed, normally through variations on the internal vowels and the use of some affixes. It may be this feature that encouraged the Egyptians to omit the vowels from their writing system. The language recognizes two genders, conventionally termed masculine and feminine; neuter meanings are expressed in the early stages of the language by the feminine, later by the masculine. It is possible that case endings, similar to those in some Semitic languages, existed at a very early stage of Egyptian, but they are not written and soon fell away. Traces may remain in the so-called construct state, where a direct genitive relationship is expressed by two nouns apparently in apposition. Grammatical function is marked by strict word order. A dual number is recognized alongside singular and plural.

The Egyptian verb has unique features. A stative tense, known in Coptic as the qualitative, seems to be inherited from an early stage of Afro-Asiatic, and has cognates in Akkadian (Egyptian). This tense expresses the result of a verbal action, and is often best rendered by an adjective or an adverbial phrase: 'open, continuous, far away, already knowing,' or the like. The narrative tense system, on the other hand, is peculiar to Egyptian, and appears to consist of various verbal nouns with possessive suffixes for subject ('his hearing' developing into 'he hears'). Other forms include a possessive construction with parallels to modern perfects ('hearing to him' developing into 'he has heard'), and an infixed series which expresses past, present, and future contingency. There is also a set of so-called active participles, which are really epithets or nouns of agent ('a hearer'), and a sequence of relative tenses formed from passive participles ('his heard one' developing into 'the one which he heard'). Participles and relative forms show two aspects, perfective and imperfective, depending on whether the action is envisaged as completed or not; there are also traces of a prospective, which has future or subjunctive force. Aspect also features in the narrative tenses, where prospective and probably circumstantial forms also occur. The language is VSO in narrative contexts, but stative constructions take the form SV. A remarkable feature is that four uses of the English verb 'to be' – existential, predicative, identifying, and partaking of a quality – are rendered by distinct constructions. On the other hand, there is no verb 'to have,' which is conveyed by periphrases such as 'there is to me.' A welcome omission is comparative inflection of adjectives: 'she is better than I' is expressed simply as 'she is good against/in respect to/ me.'

This is the form taken by Egyptian in its classic period, Middle Egyptian, during the early second millennium B.C. This canonical stage was recognized by the Egyptians themselves, and was retained in formal inscriptions until the end of Pharaonic history. However, after about 1400 B.C., pressure from the spoken language, which was constantly changing, began increasingly to affect the written texts. The result is Late Egyptian, which took over many of the functions of its predecessor. Late Egyptian, which is the direct ancestor of Coptic, stands to Middle

Egyptian rather as Italian does to Latin, although phonetic changes are often concealed by the continuity of the script. Word order is noticeably freer. The most obvious innovations are in the verb, where the old patterns are replaced by analytic expressions derived from obsolescent verbal forms. This process – which is strikingly similar to the development of modern English – leads to greater emphasis on time distinction and modal subtleties. The number of compound 'tenses' in such a system is almost limitless, although one distinction present in the last phase of Late Egyptian – that between preterite and present perfect – is lost in Coptic. One unusual feature of Late Egyptian is the existence of a second series of tenses, which throw emphasis on an adverbial adjunct. These may have originated in the relative forms ('what he heard (is) yesterday' developing into 'it was yesterday that he heard'). This system is foreshadowed in Middle Egyptian, although the details are not yet understood. The development of the verbal system makes Coptic appear an SVO language, although this is historically accidental. Coptic also dispenses with most adjectives, the passive voice, and most plurals, preferring stative paraphrases, using active third-person plural constructions, and marking the plural of nouns merely by the forms of the article, possessive adjective, or demonstrative. Late Egyptian contains many Semitic loanwords; Coptic, on the other hand, is almost as full of Greek words as modern English is of French or Latin.

Egyptian throughout its history deserves the epithet *lingua geometrica*, given to it in the 19th century, when the regularity and elegance of its constructions were first appreciated. The following examples may illustrate this. (Egyptian is conventionally transliterated into Romanized consonants.)

Middle Egyptian:

ḫ'.n	*ḥ3b.n*	*wỉ*	*ḥm.f*	*r*
arise+pa	send+pa	me	embodiment+his	to
K3š	*r*	*sn-nw*	*sp*,	*ỉb.f*
Cush	for	two+ord	occasion,	heart+his
3w	*ỉm.ỉ*	*r*	*ḫt*	*nbt*
content+stat	in+me	against	thing	any+f/sg

'As a result his majesty sent me to Nubia for a second time, his heart being pleased with me more than anything.'

Late Egyptian:

wn.ỉn		*Pr-'3*	*ḥr*	*ḥ3b.ỉ*	*r*
exist+pa	contingency	Pharaoh	upon	sending+me	to
p3	*t3*	*Nḥs*	*n*	*p3*	
the+m/sg	land	Nubian	in	the+m/sg	
sp	*mḥ-sn,*	*ỉw*	*ḥ3ty.f*		
time	filling+two,	situation	heart+his		
mtry	*ỉm.ỉ*	*m*	*šsr*		
content+stat	in+me	in	abundance		

Coptic:

ⲁϥϫⲟⲟⲥ ⲛ̄ⲥⲓ ⲟⲩⲁ ⲛ̄ⲛⲉⲥⲛⲏⲩ ϫⲉ ⲁⲛⲟⲕ
ⲛ̄ϯⲙ̄ⲡⲱⲁ ⲁⲛ ⲉⲛⲁⲩ ⲉⲡⲁⲓⲣⲉϧⲟⲥ, ⲉⲁⲓⲱⲛϩ
ϩⲛ̄ⲛⲟⲃⲉ ⲛⲁϩⲟⲟⲩ ⲧⲏⲣⲟⲩ

afjoos	nci	oua	n ne	snēu
pa+he+say+it	namely	one+m/sg	of the+pl	brother+pl

je	anok	n	ti	m	p	ša
saying	myself	not[1]	1/sg	in	the+m/sg	value

an	e	nau	e	p	angelos, eai	
not[2]	to	look	at	the+m/sg	angel, situation+pa+I	
ōnh	hn	n	nobe	na	hoou	tērou
live	in	the+pl	sin	my+pl	day	entirety+their

'One of the brethren said, "For my part, I am not worthy to see the angel, having lived in sin all my days."'

Ancient Near-Eastern Religions

M Mazoyer, Université de Paris, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

The geographical setting of Hittite civilization is the high plateaus of Asia Minor. Excavations carried out by H. Winckler at Boğazköy at the beginning of the 20th century have shown these tablelands to be the site of the ancient Hittite capital, Hattusa. This was determined by the translation of the archives of the Great Kings. In 1915, the Czech scholar Hrozny managed to decipher the Hittite language and to establish its inclusion within the family of Indo-European languages. Hittite history extends over a period of more than a millennium (from the 19th to the 8th centuries B.C.E.). Hittite religion is polytheistic; ancient Hittite texts and even present-day people speak of a 'thousand gods,' the number no doubt being a symbolic representation of an infinite number. Although the names of only 800 deities have been recorded, such a large figure emphasizes the ever-present nature and ubiquity of gods in both private and public Hittite life, and the important part the gods played. A prayer dating to the 13th century, entitled 'The Prayer to the Weather God of *pihassassi*,' contains 55 paragraphs, each describing the pantheon of a specific place in the empire during the period of its maximum extent. Each city possessed its own pantheon, yet beyond this apparent diversity it is possible to observe a basic structure, a unity of sorts within diversity: each pantheon was constituted of a main god, his consort, his mountain (which could be a simple place where divinity would be revealed), and his river or his spring. The sacralization of mountains and sources reflects the geopolitical structure of the Hittite city, which included the town, with the sacrificial altar of the main deity's temple at its center, and the countryside, its mountain, and its spring. The mountain is a masculine deity and the spring is essentially feminine. All four components – town, countryside, mountain, and spring – constitute the four elements of the Hittite city.

Beyond the basic structure, the apparent diversity among local pantheons may be explained by the linguistic background of Anatolia in the Bronze Age. In the early days of the empire, at least five languages were spoken in Asia Minor: Hattian in the bend of the Kızıl İrmak near Hattusa, Hittite in Cappadocia, Palaite in the northwest (the area that would later become Paphlagonia), Luwian in regions to the south and west, and Hurrian in the southeast. As stressed by E. Laroche, what is remarkable is the long-lasting use of each of these languages. As the Hittite realm expanded, foreign deities, despite the process of syncretism, were still honored and were continually worshipped using the original language.

The Hittite chancellery created a state cult that was hierarchically above local pantheons. This is known through records of diplomatic treaties that Hittite kings made with foreign rulers or with Anatolian vassals. These treaties referred to a list of deities that played the part of witnesses, who guaranteed the application of the treaty's clauses. The list of gods that act as witnesses named 80 deities: deities 1–22, the sun gods and the storm gods; deities 23–29, protective gods; deities 39–44, Telipinu (the founding god) and his subordinates; deities 45–51, gods of war; deities 52–60, goddesses ruling over town; deities 61–64, synopsis; deities 65–76, ancient gods; and deities 77–80, sacred elements (mountains, streams, the sky and earth, winds, and clouds). This pantheon is generally what is described as the Hittite state cult. From the days of the treaty of Suppiluliuma I with Hukkana of Huyasa (Suppiluliuma: 1344–1322 B.C.E., according to T. Bryce), deities were enumerated in almost unchanging order. This reflects a deliberate choice of the gods listed.

The Hittite pantheons, characterized by their diversity and their heterogeneity, allowed coexistence of deities of various origins. The pantheons were created during the course of Hittite history and during the various stages of Hittite expansion in Anatolia. However, due to this very diversity, a strong tendency toward organizing the mixed groups is apparent: the deities that were retained following mixing of culture groups were not selected just by chance.

Substantial portions of the examined records discovered at Hattusa (the Hittite capital) or in provincial archives (as at Masat Hüyük) concern religious tablets, and especially cultic texts. Shrines were located both in the cities and in the surrounding countryside. Places of worship were of varied nature (*É.DINGIR*, ^{NA4}: *hekur*, *sinapsi*, *hila*), and their sizes could differ considerably. The great temples of Boğazköy (Nos. 5 and 6) extended over 1200–1500 m^2, whereas the size of smaller shrines would be somewhere between 400 and 600 m^2. Some temples were surrounded by a walled-off area, or *temenos*, that acted as a sanctuary. The size of the temples and their great number of rooms indicate that they included areas with an economic function, areas that served as storage magazines, or even rooms for taking part in the preparation of cultic ceremonies (Boğazköy temple No. 4). Some shrines, such as Yazilikaya, were in the open, whereas others, such as the temples of the Hittite capital, were built with cyclopean walls.

In most sanctuaries, the deity was represented by an anthropomorphic statue. Descriptions of these statues are numerous in cultic inventories, which were reported by officials who were sent throughout Anatolia in order to collect information on local cults during the reign of Tudhaliya IV. Previously, a god would have been represented by a symbol or a stela (*huwasi*), and not in anthropomorphic form (this explains texts references to sacrifices to stelae). These stelae (monuments) were inscribed or carved with the god's image. The transition from symbolic to physical representation dates to the period of Tudhaliya IV. The storm god is depicted in the form of a gold statue holding a mace in his right hand, and another symbol in his left hand; he is standing on two mountains. The storm god could also be depicted as a bull both before and after Tudhaliya's religious reform: such is the case at Alaca Höyük (temple No. 8), where a bull is the god himself.

Some locations within a sanctuary and some cultic objects were subject to particular veneration, and for this reason played an important part in the cult. The importance of the altar is apparent in that, just like the temple, it possessed its own foundations. It was on the altar that deities' statues would stand and cultic objects would be placed. Thus, by no means can the altar be identified as being equivalent to an offering table.

The temple's windows or doors, marking the edge of the sacred and secular areas, were particularly important. Due to their function, they would be places of sacrifice, just like other sacred locations. The window is mentioned in Hittite texts as a place of communication and exchange, and is the passage through which life and death penetrate. In the myth of Illuyanka (see later), Hupasiya, the lover of the goddess Inara, was killed by her because he had looked through the window despite her warning. In a foundation myth, the king is requested to pull his children out of the window, which obviously symbolizes the promise of numerous offspring. Doors were, generally speaking, considered to be sensitive locations of the utmost importance. The essential part played by city gates in Hittite urban architecture and planning is well known (temple Nos. 9, 10, and 11), and several deities or groups of gods were in charge of their protection. Temple doors were particularly honored during rituals; specific parts, such as the wooden bolt (or *aska*), were frequently mentioned.

The temple's most crucial object was the sacrificial altar. Both unmovable and mobile/portable types of hearths are known. The unmovable hearth represents the very center of the temple and symbolizes the union between gods and human beings. It is therefore easy to understand why great care was taken in its construction. A text concerning the foundation ritual, focusing on the building of a palace, describes in detail the making of the hearth.

Among ritual objects that were particularly honored, the *kursa* (aegis?) specifically deserves mention. It was made of sheepskin and was sometimes decorated. Until recently, its was considered to be a sacred aegis/fleece, but is now seen as a hunter's bag. Nevertheless, this object's warlike character is quite obvious, thus its categorization among defensive weaponry. The *kursa* became the attribute of several gods, and it was itself divine and was worshipped in sanctuaries by priests attached to its cult. Ritual vessels for libations and for drinking in honor of the gods should also be mentioned. Many cultic vessels have been discovered in excavations (temple No. 12). Their shapes are related to the deity with whom they were associated (for instance, a bull, in the case of the storm god). They could also represent human body parts (the penis, the arm, the foot, etc.; e.g., temple No. 13). The temple was the house of the god. All things useful to him were stored there. The cult took place in part in the deity's sanctuary, i.e., in the *cella*, or in an independent building. In this room were placed the god's statue and eventually those of the deities of his 'inner circle,' or *kaluti*, as well as sacred furniture, such as his throne, his bed, or ritual objects.

The priesthood was made up of people in charge of taking care of the god. Each day, prayers would respond to the needs of the deity of whom the priests were in charge. The deity had to be washed and dressed, and food and abundant and varied drink had to be offered to him. Priests had to be clean and ritually immaculate. Some of the specific obligations of the priests to the deity are known from the lines of a text that specified the duties of priests (translation by E. H. Sturtevant):

> Then may those who prepare daily bread be pure
> May they wash and clean themselves (and) their hair
> And fingernails. May they wear pure clothes.
> If this is not the case, may they not prepare the bread.

Priests and assistants were a stratified group and were subjected to a very strict hierarchy. Men predominated among the priesthood; priestesses were relatively rare, but could play important roles, such as that of 'mother of the God,' and were attached essentially to the cult of feminine deities. Next to this priest class was a group of people who were not considered priests or priestesses, but who could be described as belonging to this category (such as the palace magician, as well as the *halliyares* and *hunepisa* (in charge of singing and chanting prayers)). Other clergy

members appear to have been assistants in the cult, including the prince's cooks, the virgins of the city of Kasha, the actor, and the wrestlers that would perform simulated fights in order to entertain the god.

Gods were not only the owners of their sanctuaries but also of the land, which did not belong to the Hittite king. The ruler was only the administrator of lands, the gods' favorite (*Tabarna*). The god's presence in his temple was the guarantee of a land's prosperity. When the king would fulfill his obligations toward the gods, the land would be rich, he would be respected by his subjects, and would impose his law and might over his foes. However, if he did not correctly carry out his obligations toward the gods, they would leave the sanctuary and take refuge in an inaccessible location. Their absence would have dramatic consequences for the land, as is described in the *Story of Telipinu*. Hence, the ruler and the clergy's first obligation was to keep the god within his temple by faithfully following obligatory procedures. The ruler had to respect ritual, keep purity and cleanliness within the god's sanctuaries, celebrate the latter's festivals by following ceremony and well-established cultic tradition, and regularly offer sacrifice. The land's first fruits and the first animal offspring of the year were specifically dedicated to the gods, and it was thought that lavish sacrifice could ensure their safeguard and generosity. Food and drink were regularly offered to them. A great number of Hittite festivals are known to have been celebrated. These could take place either simultaneously or successively in sanctuaries or places of worship in the city. Some of these festivals were itinerant and would last several days: the *AN.TAH.SUM*^{SAR} festival ('the festival of the crocus flower') went on for 38 days in several cities (e.g., Hattusa, Matilla, and Arinna).

Andean Languages

W F H Adelaar, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

'Andean languages' is a cover term for the native indigenous languages spoken in the western part of South America, more precisely in the Andean mountain ranges and the adjacent Pacific coastal strip. Genealogically, the Andean languages do not constitute a unity. They comprise some language families, most of which have a limited geographical importance, as well as several linguistic isolates (languages without proven relatives or languages that have been left unclassified so far). An 'Andean' language family proposed by Greenberg (1987) covers only part of the Andean languages and has not been generally accepted. From a typological point of view, Andean languages are also highly diverse. Many Andean languages have become extinct and cannot be classified because of a lack of data.

From north to south, the following families and isolates are encountered. In the northern and eastern parts of the Colombian Andes, several languages belong to the Chibchan family, which extends further into Central America: Barí (Motilón; also in Venezuela), Chimila, Cuna (Kuna), Damana, Ika (Aruaco), Kogui (Cogui), and Tunebo (Uwa). The Muisca (Chibcha) and Duit languages, which have been extinct since the late 18th century, also belonged to the Chibchan family. Muisca, originally spoken in the surroundings of Bogotá, was a language of administration during the colonial period. Chibchan languages share a common lexical base, but are highly diverse structurally. Some of them (Barí, Chimila) are tonal.

members appear to have been assistants in the cult, including the prince's cooks, the virgins of the city of Kasha, the actor, and the wrestlers that would perform simulated fights in order to entertain the god.

Gods were not only the owners of their sanctuaries but also of the land, which did not belong to the Hittite king. The ruler was only the administrator of lands, the gods' favorite (*Tabarna*). The god's presence in his temple was the guarantee of a land's prosperity. When the king would fulfill his obligations toward the gods, the land would be rich, he would be respected by his subjects, and would impose his law and might over his foes. However, if he did not correctly carry out his obligations toward the gods, they would leave the sanctuary and take refuge in an inaccessible location. Their absence would have dramatic consequences for the land, as is described in the *Story of Telipinu*. Hence, the ruler and the clergy's first obligation was to keep the god within his temple by faithfully following obligatory procedures. The ruler had to respect ritual, keep purity and cleanliness within the god's sanctuaries, celebrate the latter's festivals by following ceremony and well-established cultic tradition, and regularly offer sacrifice. The land's first fruits and the first animal offspring of the year were specifically dedicated to the gods, and it was thought that lavish sacrifice could ensure their safeguard and generosity. Food and drink were regularly offered to them. A great number of Hittite festivals are known to have been celebrated. These could take place either simultaneously or successively in sanctuaries or places of worship in the city. Some of these festivals were itinerant and would last several days: the *AN.TAH.SUM*^{SAR} festival ('the festival of the crocus flower') went on for 38 days in several cities (e.g., Hattusa, Matilla, and Arinna).

Andean Languages

W F H Adelaar, Leiden University, Leiden, The Netherlands

'Andean languages' is a cover term for the native indigenous languages spoken in the western part of South America, more precisely in the Andean mountain ranges and the adjacent Pacific coastal strip. Genealogically, the Andean languages do not constitute a unity. They comprise some language families, most of which have a limited geographical importance, as well as several linguistic isolates (languages without proven relatives or languages that have been left unclassified so far). An 'Andean' language family proposed by Greenberg (1987) covers only part of the Andean languages and has not been generally accepted. From a typological point of view, Andean languages are also highly diverse. Many Andean languages have become extinct and cannot be classified because of a lack of data.

From north to south, the following families and isolates are encountered. In the northern and eastern parts of the Colombian Andes, several languages belong to the Chibchan family, which extends further into Central America: Barí (Motilón; also in Venezuela), Chimila, Cuna (Kuna), Damana, Ika (Aruaco), Kogui (Cogui), and Tunebo (Uwa). The Muisca (Chibcha) and Duit languages, which have been extinct since the late 18th century, also belonged to the Chibchan family. Muisca, originally spoken in the surroundings of Bogotá, was a language of administration during the colonial period. Chibchan languages share a common lexical base, but are highly diverse structurally. Some of them (Barí, Chimila) are tonal.

Chocoan, a small family comprising two languages, Waunana and Emberá, has its largest concentration in the Pacific regions of Colombia and Panama. It is one of the rare language groups in the Americas featuring ergative case. The Emberá, who occupy an expanding territory, are locally known under different names (Catío, Sambú, Saija, etc.).

Cariban, a large family with its center of gravity in the Amazonian region and in the Guyanas, is represented in the northeast of Colombia and in adjacent Venezuela by Opón-Carare (extinct), Yukpa (Motilón), and Japreria. Several extinct languages of the Magdalena valley received Cariban influence (Muzo, Colima, Panche, Pijao), although their exact classification remains undecided.

The Arawakan family, also one of the major Amazonian groupings, is represented on the Guajira peninsula, west of Lake Maracaibo, by two verb-initial languages, Guajiro (Wayuu) and Paraujano (Añú), a rarity for the Andean region. The Guajiro, with a population of about 300 000, are one of the fastest-growing indigenous groups in South America. Two small families, both extinct – Timote-Cuica and Jirajaran – were confined to the Venezuelan part of the Andes and its Caribbean foothills.

In the southern Andes of Colombia and adjacent Ecuador, the Barbacoan language family has five living members: Cayapa (Cha'palaachi, Chachi), Colorado (Tsafiki), Cuaiquer (Awa Pit), Guambiano, and Totoró. Several extinct languages (Cara, Pasto) may have belonged to this family, which extended from the highlands to the Pacific Coast. In addition, several linguistic isolates are found in southern Colombia: Kamsá (Sibundoy), Páez (Nasa Yuwe), and the extinct Yurumanguí. On the coast of northwestern Ecuador, the extinct Esmeraldeño (Atacame) language was also an isolate.

The central Andean region, which comprises the highlands and coast of Ecuador, Peru, and Bolivia, as well as northern Chile and northwestern Argentina, is dominated by two language families: Quechua(n) (*see* **Quechua**) and Aymaran (*see* **Aymara**). Both language groups are very similar from a phonological and structural point of view, and they share more than 20% of their lexicon. The Quechumaran hypothesis, which rests on these similarities, assumes that the two groups developed from a common source. However, nearly all the similarities can be explained by intensive contact (convergence), leaving the genealogical classification of both groups undecided. Quechua has about 8 000 000 speakers and is divided into numerous dialects with a limited degree of mutual intelligibility. Its territory extends from southern Colombia to northwestern Argentina with several interruptions. Aymaran comprises two, possibly three languages: Aymara (with over 2 000 000 speakers in Bolivia, Chile, and Peru), Jaqaru, and Cauqui (both in Peru). The typically agglutinating ('Altaic') structure based on suffixation of these languages has been considered characteristic for Andean languages, but the other languages in the region do not seem to share it in all respects. The Uru-Chipaya family, with one surviving language in Bolivia (Chipaya), has a different structure with some prefixation (along with suffixes) and extensive gender agreement.

The remaining languages of the central Andean region are all presumably extinct. They include (partly) documented languages, such as Atacameño (in northern Chile), Mochica (on the coast of northern Peru), and Puquina (in the border region of Bolivia and Peru). Some Puquina vocabulary (combined with Quechua morphology) survives in a professional language used by the Callahuaya herb doctors in Bolivia. Atacameño (Kunza) and Mochica are isolates, but Puquina may be distantly related to Arawakan. There is ample evidence of other, minimally documented languages: Panzaleo and the Puruhá-Cañar group in highland Ecuador, the Tallán-Sechura group (on the coast of northern Peru), Chacha and Culli (in the highlands of northern Peru), Quingnam (on the coast of central-northern Peru), Diaguita (in northwestern Argentina and in Chile), and Humahuaca (in northwestern Argentina). In addition, in Argentina the Lule or Tonocoté language (extinct but documented) presumably had its origin in the Chaco region.

In the southern Andes, Mapuche (Mapudungun; also known as Araucanian) is the native language with the largest distribution. Originally the dominant language of Chile, it is now confined to an area in southern Chile (Biobío, Malleco, Cautín, Arauco, etc.) and several locations in the Argentinian pampas and in Patagonia. Its number of speakers may be close to 500 000 (no reliable count is available). The closely related Huilliche (Tsesungun) language, originally spoken in Osorno Valdivia and on the isle of Chiloé, is nearly extinct. Mapuche is an agglutinating, suffixing language, as are Quechua and Aymara, but it differs from these languages in that it has practically no nominal morphology. By contrast, its verbal morphology is exceptionally rich. Some of its characteristics (interdental consonants, lack of case, noun incorporation) cause the Mapuche group to stand alone among the Andean languages. It has no known relatives. In the Argentinian region of Cuyo (Mendoza, San Juan), the unrelated Huarpean group (with the languages Allentiac and Millcayac) was spoken until the 17th century.

In the southern tip of Chile, the isolates known as Kawesqar (Qawasqar) or Alacaluf (in the

archipelago west of the mainland) and Yahgan or Yamana (on the islands south of Tierra del Fuego) are both close to extinction. A third language, Chono (north of Kawesqar), has long been extinct. The Chon family, which comprises Ona or Selknam (on Tierra del Fuego), Tehuelche, Teushen, and Gününa Yajich (all in southern Argentina), is now only represented by Tehuelche, which is also nearly extinct.

An issue under debate is the affiliation of languages or language families situated on the eastern fringe of the Andes. From a genealogical viewpoint, this area is exceptionally diverse. Some of these languages share characteristics with Amazonian groups (e.g., 'Amazonian' classifiers, extensive prefixation, loose morphology, rich vowel systems, nasal harmony), whereas others are closer to Andean languages and seem to have had some relationship to the languages spoken in the highlands. Among the latter are Betoi and Cofán in Colombia (the latter also in Ecuador), the Jivaroan languages and the Candoshi group (in Ecuador and northern Peru), the Cahuapanan and Hibito-Cholón groups (in northern Peru), and a series of isolates on the Andean slopes of northern and eastern Bolivia (Leco, Mosetén, Movima, Yuracaré). Amuesha (Yanesha) found in Peru is an Arawakan language with a heavy Quechua admixture.

Because of massive language extinction, many Andean languages have disappeared during the last 500 years, leaving an incomplete picture of the original situation. It is not easy to link known languages to specific cultures established by archaeologists. Most of the extinct languages were replaced by expanding local languages, such as Quechua, Aymara, and Mapuche, or by Spanish (now spoken by a majority of the population).

Andorra: Language Situation

P Gonzalez, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Andorra is in southwestern Europe, situated in the eastern Pyrenees between France and Spain. It is a very small principality, only 464 km^2, with a population of 72 320 inhabitants (Ministry of Finance, 2002). Andorra was once an isolated piece of land, but nowadays it is a prosperous and rich country mainly because of tourism, as it is a well-known center for winter sports, and its status as a tax heaven between Spain and France.

It has been said that Charlemagne founded Andorra in 805 in recognition for its inhabitants' support in his campaigns in Northern Spain. The political power over the Andorran territory was passed eventually to the bishop of Urgell (in Catalonia). In the 11th century, a dispute arose between the bishop and his northern French neighbor over Andorra. In 1278, the conflict was resolved by the signing of two arbitration

Andorra: Language Situation

P Gonzalez, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Andorra is in southwestern Europe, situated in the eastern Pyrenees between France and Spain. It is a very small principality, only 464 km^2, with a population of 72 320 inhabitants (Ministry of Finance, 2002). Andorra was once an isolated piece of land, but nowadays it is a prosperous and rich country mainly because of tourism, as it is a well-known center for winter sports, and its status as a tax heaven between Spain and France.

It has been said that Charlemagne founded Andorra in 805 in recognition for its inhabitants' support in his campaigns in Northern Spain. The political power over the Andorran territory was passed eventually to the bishop of Urgell (in Catalonia). In the 11th century, a dispute arose between the bishop and his northern French neighbor over Andorra. In 1278, the conflict was resolved by the signing of two arbitration

judgments, known as the *Pariatges*, between the bishop of Urgell and the count of Foix (in Occitania). The *Pariatges* established the co-sovereignty of the two rulers over Andorra, recognizing equality of rights, and thus gave the small principality its territory and political form. Andorra continues nowadays to be a co-principality, with the bishop of Urgell and the president of the French Republic as the co-princes by personal title and in absolute equality. Therefore, not only its geographical situation but also its history explain the influence of the Spanish and the French languages in Andorra.

Catalan (Catalan-Valencian-Balear) is the only official language of Andorra. Catalan is a Romance language of the Western Branch that is also spoken in Catalonia (Spain), North Catalonia (France), and in Sardinia (Italy). Catalan is the only language used in administrative and official affairs. In the streets, however, Spanish is widely spoken, followed by Portuguese and French. This is not surprising if one realizes that Andorrans constitute a minority in their own country; only 33% of the Andorran population are Andorran nationals. The largest group of foreign nationals are Spanish (43%), followed by Portuguese (11%) and French (7%).

The linguistic situation in Andorra is as follows: although Catalan is the official language, it is possible to live in Andorra without speaking it. However, only 3% of the population in 1995 admitted not understanding Catalan at all. Catalan is not being used in the commercial sector or in tourist activities. Other languages have taken over in non-administrative affairs. The Spanish language plays a huge role in this country. There is a large community of Spanish speakers, but they are not the only ones who use Spanish in public: many Catalan speakers use Spanish whenever they leave their homes (in shops, restaurants, etc.). French is still of great cultural importance, and the educational system is built on the French model. In the areas that border France, French is the predominant language in commerce. Portuguese is spoken in family circles, but Portuguese speakers often switch to Spanish as soon as they leave their homes, even if they are addressing another Portuguese speaker.

In January 2000 a new law was passed that installed the linguistic rights and duties of the Catalan language and regulated the situations in which Catalan should be used, addressing a perceived need to regulate and normalize the use of Catalan in Andorra.

Angola: Language Situation

R Halme, Finnish Evangelical Lutheran Mission, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Languages of Angola

Documentation of the complex language situation in Angola is very scarce. The unstable political situation that prevailed in the country from its independence in 1975 (and even before that) until the first half of 2002 has been blamed for the lack of up-to-date data. The estimates of the population of Angola range from 11 million (2004 est., CIA) to 13.6 million (2003 est., UN). Language statistics presented in this article are largely based on the information to be published in the 15th edition of the *Ethnologue*.

According to the *Ethnologue*, Angola has 41 languages belonging to three different language families. The Institute for National Languages in Luanda (Instituto de Línguas Nacionais, ILN) gives a list of 11 language groups, each with a number of subgroups. Angola shares many languages with its neighboring countries, Congo, the Democratic Republic of Congo (DRC), Zambia, and Namibia.

Bantu Languages

The Angolan Bantu Languages with the largest number of speakers are given in **Figure 1.** It is estimated that four million people speak Umbundu (belonging to the language group R.10 according to the referential classification by Malcolm Guthrie) as their mother tongue, mainly in the central plateau and along the central section of the coast. The fact that Umbundu was extensively used by the political party UNITA made it an important second language for people in close contact with UNITA on one hand, and may well

The Institute for National Languages in Luanda (Instituto de Línguas Nacionais, ILN) gives a list of 11 language groups, each with a number of subgroups. Angola shares many languages with its neighboring countries, Congo, the Democratic Republic of Congo (DRC), Zambia, and Namibia.

Bantu Languages

The Angolan Bantu Languages with the largest number of speakers are given in Figure 1. It is estimated that four million people speak Umbundu (belonging to the language group R.10 according to the referential classification by Malcolm Guthrie) as their mother tongue, mainly in the central plateau and along the central section of the coast. The fact that Umbundu was extensively used by the political party UNITA made it an important second language for people in close contact with UNITA on one hand, and may well

Figure 1 Angolan Bantu languages with the largest number of speakers.

have restricted its usage in the areas governed by the MPLA on the other. Loanda Mbundu or Kimbundu (H.20) is usually taken as the second largest language in Angola, with about three million speakers. However, figures produced by the Angolan National Institute for Statistics (Instituto Nacional de Estatística, INE, 1999, as cited in Hodges, 2001) show that the percentage of Loanda Mbundu speakers has decreased from 23 in the 1960 census to only 15 in the survey of 1996. Loanda Mbundu is spoken in the northern part of Angola, in the capital, Luanda, and its surroundings. Linguistic varieties closely related to Loanda Mbundu include Nsongo, Sama, and Bolo. The third widely spoken Angolan language is Kongo or Kikongo (H.10), with more than one million speakers in northern Angola. The *Ethnologue* has separate entries for Kongo San Salvador and Yombe, both spoken in the enclave of Cabinda. In Angola, the people of Cabinda are often referred to as speakers of Fiote, which is given in the *Ethnologue* as an alternative name for West Kongo, a dialect of Kongo.

Chokwe (K.10 in Guthrie's and K.20 in SIL's classification) has about half a million speakers from the northeastern corner to the central and southern parts of Angola. In addition to Chokwe, the *Ethnologue* lists eight other languages for Angola belonging to this language group: Luchazi, Nyemba, Mbwela, Luvale, and Mbunda, each with an estimated 100 000–250 000 speakers, and Luimbi, Nkangala and Nyengo, each with fewer than 50 000 speakers in Angola. Fleisch (2000) added Yauma to this group and claimed that most of these dialects are mutually intelligible. These languages have speakers in the central and southeastern parts of Angola. In Angolan official contexts this language cluster (with the exception of Chokwe) has been referred to as Mbunda or Ngangela.

According to Ntondo (1998: 75), Kwanyama (R.20) has about 350 000 mother-tongue speakers in southern Angola near to the Namibian border. The other two Wambo varieties listed by the *Ethnologue*, Ndonga and Ngandyera, are hardly spoken in Angola. The Wambo variety in the western part of Kunene province, near Xangongo, is Mbandja. All of the Wambo languages are mutually intelligible.

Languages of the southwestern part of Angola include Nyaneka (R.10), Nkhumbi (R.10), and Zemba (R.30). Nyaneka and its closely related varieties Mwila, Humbe, and Ngambwe are spoken by about

300 000 people. Nkhumbi is spoken by an estimated 150 000 people in Angola, along the Kunene River. Zemba, Twa, Hakavona and Himba are part of an extended dialect continuum, where the last mentioned is closest to Herero, spoken in Namibia.

Lunda (K.20 Guthrie, K.30 SIL) and Ruund, closely related to Lunda, have approximately 200 000 speakers in Angola, in the northwestern province Lunda Norte and in the very eastern part of the province of Moxico. Holu (H.30 Guthrie, K.10 SIL), with fewer than 30 000 speakers, is spoken in the north in the Cuango River area on the border with the DRC. Yaka (H.30), together with a related variety, Mbangala, are estimated by SIL to be spoken by more than 200 000 people in the north central part of the country. Meeuwis (2003) reported that Lingala, a lingua franca widely spread in the DRC and Congo, has mother-tongue speakers also in Angola. Kwangali (K.30 Guthrie, K.40 SIL), Mbukushu (K.40) and Diriku (K.60 Guthrie, K.70 SIL), languages of Okavango and Caprivi, are spoken along the Namibian border.

Portuguese

A survey made by the INE in 1996 (as reported by Hodges, 2001) claims that Portuguese is the mother tongue of 26% of the Angolan population. One should be cautious in drawing conclusions on these statistics, since although the survey was conducted in all 18 provinces, more attention was probably given to the urban than to the rural areas with restricted accessibility. Also the language that was used as a medium of interaction while conducting the survey may have skewed the statistics. However, it is clear that the number of mother-tongue speakers of Portuguese is increasing, and it is far greater than 57 600, an estimate from 1993.

The long interaction between Portuguese and the other languages of Angola has led to lexical borrowings (in both directions) as well as adoption of phonological and syntactic features from African languages in Portuguese.

Khoisan Languages

Most of the people speaking Khoisan languages live in the southeastern part of the country. Kung-Ekoka or !Kung, which is estimated to have fewer than 2000 speakers in Angola, !O!ung, with more than 5000 speakers, and Maligo, with more than 2000 speakers, belong to the Northern Khoisan language family, whereas Kxoe or !Hukwe, with some 100 speakers in Angola, north of Caprivi, belongs to the Central Khoisan language family.

Languages in Angolan Society

Official Status

Portuguese is Angola's only official language. After independence, the Angolan government named six national languages to be studied, developed and promoted. These languages were Kongo, Loanda Mbundu or Kimbundu, Mbunda (which was later changed to Ngangela), Umbundu, Chokwe and Kwanyama.

The constitutional law that dates from November 11th, 1975, with the latest revision from 1992, does not include any statement about languages. The Constitutional Commission declared in 2000 as one of its fundamental principles in preparing the new constitution to value the national languages and their promotion, study, teaching, and usage, as well as to define Portuguese as the official language.

In June 2004 a proposal for a statute on national languages was being discussed in Angola. The proposed law states that any language historically used by Angolan peoples is to be regarded as a national language, irrespective of the number of speakers. It aims at institutionalizing the usage of the national languages and emphasizes the need for their development and promotion (Gourgel, 2004).

Language Standardization and Formal Education

The ILN works for the standardization and promotion of the national languages. Language-engineering tasks have also been performed by churches and NGOs that promote literacy. The United Nations Development Programme (UNDP) has assisted the institute in organizing research projects with the aim of creating alphabets for the national languages (ILN, 1980; Ntondo, 1998: 78). The ILN has produced grammars and vocabularies for the six selected languages, although not always of the best scientific quality. Most of the languages of Angola still lack a standardized norm.

Portuguese is the only language used as a medium of instruction in the formal education system of Angola. The Ministry of Education organized a national consultation on education (the UNESCO program Education for All) in Luanda in April 2004. The participants identified the following problems related to language and learning: the poor knowledge of Portuguese by learners and of local languages by teachers, and the nonuse of the local languages and sign language in the education system. It is planned to implement the national languages in primary education in 2005 (Amélia Mingas, personal correspondence, 2004). Both the Catholic University of Angola and the Agostinho Neto University are prepared to assist in teacher training together

with the Ministry of Culture, which is also engaged in producing didactic material in the national languages.

The literacy rate was estimated at 49% in 2000. Literacy projects are operated in Portuguese and in eight national languages, including Ibinda and Nyaneka-Humbi (Nyaneka) (UNESCO, 2003).

Literature, Press, and Broadcasting

The churches have been active in printing in African languages. In the colonial time all books and leaflets were either bilingual or exclusively in Portuguese, because it was strictly prohibited to have any publication in an African language without having the same content printed in Portuguese.

Most modern Angolan literature is in Portuguese. However, there are books, or parts of books, in the national languages. All Angolan daily and weekly newspapers at the national level use exclusively Portuguese.

The Televisão Pública de Angola (TPA) broadcasts most of the time in Portuguese. It produces informative programs in Kongo, Loanda Mbundu or Kimbundu, Ngangela, Umbundu, Chokwe, Kwanyama, and Fiote. These languages, together with Luvale, Nsongo, Lunda, Mbangala, and Nyaneka, are the languages of broadcasting on the radio channel N'gola Yeto. It is a separate channel of the Rádio Nacional de Angola (RNA) for the national languages. Three other channels of the RNA and the catholic Rádio Ecclesia broadcast nationwide in Portuguese.

The Angolan Language Situation in Change

About a million people died as a consequence of the Angolan civil war, which lasted for almost 30 years. According to the United Nations Office for the Coordination of Humanitarian Affairs, 4.29 million people were internally displaced in Angola in January 2002. Two years later, nearly all of them had either returned to their areas of origin or resettled in their host communities. At the beginning of 2004, half of the refugees, estimated at 450 000, had returned home from the countries bordering Angola. These migratory movements have certainly affected the language situation. Further, the accelerated urbanization led to an increase in the number of mother-tongue speakers of Portuguese.

In the colonial time, the national languages were said to be 'languages of dogs.' The acquisition of Portuguese was a prerequisite for Angolans to become citizens with full rights. Portuguese has remained the language of the elite after independence. Mufwene (2002) claimed that "shifting to a particular language is typically associated with particular benefits to be derived from its usage, especially economic benefits." This is true for many Angolan families where the parents do not see any point in passing their mother tongue to their children. Although Portuguese still is the key to economic success, the national languages are also being valued more and more, and attitudes are changing to the benefit of multilingualism at both national and personal levels (Matondo Tomalela, personal correspondence).

Anguilla: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of Anguilla is English and 8000 of the 13 008 inhabitants speak it. It exists in a continuum with the other language of the island, Leeward Caribbean Creole English. This has 13 000 speakers although many villagers deny using it. Leeward Caribbean Creole English, although mainly spoken in Antigua and Barbuda, exists in a dialect continuum across the entire region and there are also significant numbers of speakers in Dominica, Montserrat, and St. Kitts-Nevis. The creole is partly mutually intelligible with Jamaican (Southwestern Caribbean Creole English) and possibly with the Bahamas creoles (Bahamas Creole English). Literacy is 95%.

Unlike many other islands in the Leeward group, Anguilla was found to be unsuitable for sugar cane production (*see* **Antigua and Barbuda: Language Situation**). This meant that the island was spared some of the immense social and linguistic changes wrought by the importation of slaves and the deprivations of the plantation system (*see* **Antigua and Barbuda: Language Situation** and **Barbados: Language Situation**).

Animal Communication Networks

T Peake, Copenhagen University, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

In nature, animals communicate, produce and receive signals, in an environment containing many other animals simultaneously producing and receiving signals, an environment that can be characterized as a network. A 'communication network' describes any system having at least one of two defining properties: (1) a given signal can be potentially received by more than one individual and (2) receivers can potentially receive more than one signal at a time. A network thus consists of several individuals that at any one time may be signaling or receiving signals and whose roles (signaler or receiver) may change dynamically. Examples that clearly fit these properties include dense aggregations of communicating individuals such as frog and insect choruses or social grouping systems. Here, the obvious proximity of signaling individuals means that studies have long incorporated the idea of communication in a network environment. However, even systems in which individuals are less densely distributed may be characterized as communication networks as many signals are adapted to transmit over long distances. For example, in territorial songbirds where individuals defend exclusive areas, the transmission range of signals used (songs) frequently extends over a number of territories; thus, a given signal can potentially be received by many conspecifics. In such systems, a network approach to the evolution of signals and signaling behavior, although potentially equally important, is much less widely used.

The explicit consideration of communication occurring in networks is a relatively recent one that arose from the dissatisfaction felt by some researchers with the limitations of theoretical models based on a simple dyadic communication system. The majority of models of communication (and hence the majority of empirical research) characterize communication as being a process of information transfer between a single signaler and receiver – a signaler–receiver dyad. Thus, the costs and benefits of signaling or responding to signals are considered only within the dyad; costs and benefits accruing due to the wider social environment are rarely considered explicitly. There are two main reasons for this: (1) the problem of many signalers and receivers acting simultaneously and switching roles dynamically is mathematically difficult and (2) the practicalities of measuring simultaneously the signaling outputs of a large number of individuals in the field have only recently been addressed with the advent of affordable, portable multichannel recording devices, and analysis time is considerable and experimental design complex. Practical problems have been tackled more

In nature, animals communicate, produce and receive signals, in an environment containing many other animals simultaneously producing and receiving signals, an environment that can be characterized as a network. A 'communication network' describes any system having at least one of two defining properties: (1) a given signal can be potentially received by more than one individual and (2) receivers can potentially receive more than one signal at a time. A network thus consists of several individuals that at any one time may be signaling or receiving signals and whose roles (signaler or receiver) may change dynamically. Examples that clearly fit these properties include dense aggregations of communicating individuals such as frog and insect choruses or social grouping systems. Here, the obvious proximity of signaling individuals means that studies have long incorporated the idea of communication in a network environment. However, even systems in which individuals are less densely distributed may be characterized as communication networks as many signals are adapted to transmit over long distances. For example, in territorial songbirds where individuals defend exclusive areas, the transmission range of signals used (songs) frequently extends over a number of territories; thus, a given signal can potentially be received by many conspecifics. In such systems, a network approach to the evolution of signals and signaling behavior, although potentially equally important, is much less widely used.

The explicit consideration of communication occurring in networks is a relatively recent one that arose from the dissatisfaction felt by some researchers with the limitations of theoretical models based on a simple dyadic communication system. The majority of models of communication (and hence the majority of empirical research) characterize communication as being a process of information transfer between a single signaler and receiver – a signaler–receiver dyad. Thus, the costs and benefits of signaling or responding to signals are considered only within the dyad; costs and benefits accruing due to the wider social environment are rarely considered explicitly. There are two main reasons for this: (1) the problem of many signalers and receivers acting simultaneously and switching roles dynamically is mathematically difficult and (2) the practicalities of measuring simultaneously the signaling outputs of a large number of individuals in the field have only recently been addressed with the advent of affordable, portable multichannel recording devices, and analysis time is considerable and experimental design complex. Practical problems have been tackled more

successfully than theoretical ones; hence, empirical work demonstrating network effects is far advanced over theory.

Within networks, benefits and costs to both signalers and receivers appear that are not apparent in dyadic considerations. These costs and benefits are detailed separately here for receivers and signalers, although in practice they operate simultaneously within a network.

Receivers in Networks

Receivers surrounded by signaling individuals face problems in locating a particular signal or signaler in a noisy environment. Such problems may be overcome by perceptual or behavioral adaptations. A commonly cited example is that of an adult penguin returning from the sea and attempting to find his or her chick in a crèche of several hundred similar chicks. Both parent and offspring vocalize extensively during the searching progress and can locate the signals of the other, even when embedded in high levels of background noise.

A potential benefit to receivers in networks arises because several signals may be received at the same time (network property 2, above). This presents an enhanced opportunity to gather information for at least two reasons. First, the fact that many signalers are operating simultaneously means that information from a number of sources can be compared directly. Many features of signalers correlate with aspects of their signaling behavior; so, for example, a female attempting to find a mate could reduce searching time by directly comparing the signals of surrounding males. Second, at any one time, some signalers will be involved in direct interactions with one another involving the exchange of signals, e.g., during aggressive or mating encounters. Signals used in this context are likely to provide particularly reliable information due to the need for signalers to perform effectively when confronted directly by a rival or a potential mate. The extraction of information from signaling interactions by third-party receivers has been termed eavesdropping and provides a means of assessing the abilities of future rivals or mates without the costs (e.g., metabolic costs, threat of harassment or direct injury) involved with direct interaction. Eavesdropping allows the extraction of information from interactions, above that available in the individual outputs of those involved; the way signals are used during interactions provides information not simply contained in the signals used. The phenomenon of eavesdropping has become central to the communication network idea largely because it provides the most compelling empirical support for the importance of a network view of animal communication.

In songbirds, the evidence is particularly strong as acoustic playback allows songbirds to be presented with acoustic signals in isolation from other potentially confounding aspects of morphology or behavior (difficult to achieve within a visual signaling system). In order to show that an animal has eavesdropped, it is necessary to show that the behavior of individual receivers is dependent on information available only in an interaction. By simulating singing interactions in the field between two loudspeakers, it has been shown that male nightingales respond more strongly to the leaders of interactions than followers. Similar experiments have involved simulating interactions outside the territory boundary of male great tits in which songs from one loudspeaker overlapped songs of the other (a highly aggressive singing strategy). The response of subject males to subsequent intrusion (again simulated by playback) showed that subjects paid close attention to the interactions and followed the roles of individual performers. In both experiments, 'interactants' differed only in the timing of songs relative to one another. This information is available only in the interaction as a whole; i.e., the timing information cannot be deduced from the individual outputs of interactants alone; thus, subjects must have eavesdropped.

In the natural situation, male great tits likely have prior knowledge of the qualities of neighboring males due to repeated encounters. One experiment gave subjects prior experience with an individual (A) using interactive playback to simulate intruders either more or less aggressive than the subject. An interaction between this known male (A) and an unknown male (B) was then simulated by playback outside the subject's territory, potentially allowing the subject to use A as a yardstick against which to measure the performance of B. Subjects indeed integrated this information, demonstrating that wild birds have the ability to perform some form of simple reasoning to deduce the status of a territorial intruder relative to itself.

Not all such experiments have focused on males as receivers. Experiments have examined the extrapair behavior of mated females when given the opportunity to eavesdrop on interactions staged using playback on their mates and neighbors. Female great tits presented with information that the neighbor was better at expelling intruders than their mate were more likely to subsequently investigate those neighbors' territories. Female black-capped chickadees have been shown to base reproductive decisions on information gathered in this way. Females mated to dominant males that lost to simulated intruders were found to

have a higher proportion of offspring in the nest sired by fathers other than their mate. Thus, the costs of being eavesdropped on may be high.

These experiments demonstrate that songbirds are capable of eavesdropping, but say little about whether birds actually do eavesdrop. A recent study followed the movements of radio-tagged male nightingales while neighboring males interacted with intruders simulated by playback. Tagged males intruded onto the territories of neighbors during these interactions, intruding sooner when interactions were more intense, strongly suggesting that males do indeed eavesdrop.

Similar experimental approaches have been used to investigate the extent of eavesdropping on visual signals used during aggressive interactions in teleost fish. In this case, fish are allowed to witness interactions between others and the subsequent response to winners and losers compared with the response shown to winners and losers that had not been seen. Both male and female fish respond differently to seen winners and losers while showing no response difference to unseen winners and losers; thus, information was extracted from the interaction. These results are consistent with eavesdropping, but are not conclusive due to the difficulties of removing potential sources of information not related to communication (e.g., physically aggressive behaviors).

Signalers in Networks

The most immediate problem for signalers is in getting their message across to the intended receiver(s). An environment containing many signalers competing for attention limits the effective transmission range of the signal and requires signaling strategies that enable signals to be transmitted successfully, e.g., timing signals carefully, raising signal production as competition increases, or directing signals to particular receivers.

Given the potential importance of information transmitted to eavesdroppers (see above), one might expect individuals involved in interactions to either enhance (when performing well relative to opponents) or reduce (if performing badly) information transferred to potential eavesdroppers. Indeed, there are examples of behaviors that reduce or enhance information transfer to others during aggressive encounters. In a number of songbird species, interactants engaged in particularly intense song duels switch from loud aggressive signals to quiet signals that transmit only short distances as the intensity increases; this reduces information transfer during times when interactants are particularly vulnerable. In other species, loud, visually obvious 'victory' displays may be produced by the winner of a contest, leaving surrounding individuals in no doubt as to the outcome. In this case, the intended receivers of the victory display are those individuals that may have been eavesdroppers during the interaction. The changes in behavior of interacting individuals aware of the presence of potential eavesdroppers have been termed 'audience effects'. Audience effects in this context have yet to be investigated experimentally in songbirds, but the presence of potential eavesdroppers can have marked effects on the behavior of interacting fish. In the presence of watching females, interacting male Siamese fighting fish decrease directly aggressive behaviors and increase conspicuous aggressive visual displays. In the presence of a male audience, males 'winning' an interaction do not change their behavior, but those 'losing' reduce display intensity, reducing information transfer to the audience. The influence of social environment on communication may be more complex, however, as recent studies suggest that these types of experiments may have overestimated audience effects due to preexposure of interactants to audiences, causing increased aggressive motivation.

Implications of Networks

Recognition of the fact that communication occurs in a social environment is not new; social context is implicit in a number of models of communication and a major consideration in the design of field experiments. However, empirical studies that explicitly explore the social environment within which communication naturally occurs are a new development and provide compelling evidence for its importance in the evolution of communication systems. Despite this evidence, the current theoretical framework rarely considers the social environment explicitly. For example, there are currently no models that enable us to make predictions about when, where, and how the extraction of information by eavesdroppers is favored or to predict the effects of eavesdroppers on the use of particular aggressive strategies. A recent game theory model that included an eavesdropping strategy found that eavesdropping was stable at only a low level as eavesdroppers were unable to predict how other eavesdroppers would behave; this represents a limitation of the model rather than an accurate representation of the world but highlights the difficulties of including such strategies effectively. In some areas, specific models that fit well with empirical data have been developed, for example, models that predict calling strategies in

dense frog choruses. Similar models are being developed for other taxa and it is likely that such an approach will be of great benefit in understanding all aspects of the evolution of communication.

Animal Communication: Deception and Honest Signaling

R Bshary, University of Neuchâtel, Neuchâtel, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

The Problem

Evolutionary theory has a very clear and precise view on the function of communication: the sender emits signals to manipulate receiver behavior to the sender's benefit (Dawkins and Krebs, 1978). If there is no signaling benefit to the sender, no signaling takes place. This insight raises two important questions that are intimately linked to each other: (1) Why should receivers ever pay attention to signals if their response supposedly benefits someone else? (2) How accurate is the information transferred by the signaler? For example, could a weak male emit deceptive signals to pretend that he is the biggest shot in town to attract females for mating? If not, what mechanisms keep signals honest so that it may pay receivers to extract information relevant for their own fitness? As outlined below, evolutionary biologists have come up with a variety of answers to these problems.

No Conflict between Sender and Receiver

Under a variety of circumstances, the benefits for the signaler coincide with benefits for the receiver, so there is no conflict of interest. The signal should be honest and the receiver should respond appropriately to its meaning. Conflict is often absent (or at least reduced) if sender and receiver are genetically related (Hamilton, 1964). A parent giving an alarm call when spotting a predator to make its offspring and other relatives move into shelter still signals according to evolutionary theory (it increases its fitness by manipulating the behavior of someone else) but it is clearly also in the interest of the relatives to respond to the alarm call.

Also between unrelated individuals, there may be situations where there is no conflict between sender and receiver. To stay with the example of alarm calls (references in Bshary and Noë, 1997), it may pay individuals to give alarm calls to warn unrelated group members if (a) the response increases movement activity that may make it difficult for a predator to single out any individual prey, including the signaler ('confusion effects'), (b) the response is that one or several alerted individuals protect group members, including the signaler, against the predator, or (c) by increasing the survival probability of group members, the alarming individual might receive default future benefits through group augmentation (Kokko *et al.*, 2001). For example, larger groups may have more helpers to raise offspring of the signaler or may be more likely to defend resources against neighboring groups.

dense frog choruses. Similar models are being developed for other taxa and it is likely that such an approach will be of great benefit in understanding all aspects of the evolution of communication.

Animal Communication: Deception and Honest Signaling

R Bshary, University of Neuchâtel, Neuchâtel, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

The Problem

Evolutionary theory has a very clear and precise view on the function of communication: the sender emits signals to manipulate receiver behavior to the sender's benefit (Dawkins and Krebs, 1978). If there is no signaling benefit to the sender, no signaling takes place. This insight raises two important questions that are intimately linked to each other: (1) Why should receivers ever pay attention to signals if their response supposedly benefits someone else? (2) How accurate is the information transferred by the signaler? For example, could a weak male emit deceptive signals to pretend that he is the biggest shot in town to attract females for mating? If not, what mechanisms keep signals honest so that it may pay receivers to extract information relevant for their own fitness? As outlined below, evolutionary biologists have come up with a variety of answers to these problems.

No Conflict between Sender and Receiver

Under a variety of circumstances, the benefits for the signaler coincide with benefits for the receiver, so there is no conflict of interest. The signal should be honest and the receiver should respond appropriately to its meaning. Conflict is often absent (or at least reduced) if sender and receiver are genetically related (Hamilton, 1964). A parent giving an alarm call when spotting a predator to make its offspring and other relatives move into shelter still signals according to evolutionary theory (it increases its fitness by manipulating the behavior of someone else) but it is clearly also in the interest of the relatives to respond to the alarm call.

Also between unrelated individuals, there may be situations where there is no conflict between sender and receiver. To stay with the example of alarm calls (references in Bshary and Noë, 1997), it may pay individuals to give alarm calls to warn unrelated group members if (a) the response increases movement activity that may make it difficult for a predator to single out any individual prey, including the signaler ('confusion effects'), (b) the response is that one or several alerted individuals protect group members, including the signaler, against the predator, or (c) by increasing the survival probability of group members, the alarming individual might receive default future benefits through group augmentation (Kokko *et al.*, 2001). For example, larger groups may have more helpers to raise offspring of the signaler or may be more likely to defend resources against neighboring groups.

An intriguing argument for conflict-free honest signaling in the context of mate choice uses the following logic (Wedekind *et al.*, 1995): Sexual recombination serves to get optimal allele diversity on the major histocompatibility complex (MHC), the region of the genome that codes for defense against all sorts of parasites and diseases. Therefore, there might not be a single ideal partner for all members of the opposite sex but the best partner has complementary alleles. In that case, the best strategy would be to advertise one's own allele composition honestly in order to get the most suitable partner.

Potential Conflicts of Interest between Signaler and Receiver

Investigating communication becomes most interesting when interests between sender and receiver can be sometimes coinciding and sometimes conflicting. Consider an interaction between a cleaner fish and a predatory client (Figure 1). The predator opens its mouth as a signal to invite mouth inspection by the cleaner, which removes parasites and remaining food particles. As long as the signal is honest, both sides benefit. The predator gets its mouth cleaned and the cleaner fish gets a meal. However, the predator might sometimes be so hungry that eating the cleaner would yield a higher benefit than ectoparasite removal ('eating is cheating'). Under such circumstances, the cleaner might be better off ignoring the invitation for mouth inspection.

From an evolutionary perspective, no relationship is free of conflicts unless individuals are genetically identical. Even between parents and offspring, conflicts may occur, e.g., over parent food provisioning rates or how parents distribute food among siblings (Trivers, 1974). Whenever the interests of sender and receiver are different, the sender would profit from sending deceptive signals that elicit the receiver's best response for the sender's fitness. But deceptive signals would select for receivers that simply ignore the signals, and communication would eventually break down. So what forces keep signals honest? Zahavi (1975) found a simple and powerful solution, which was mathematically formalized by Grafen (1990): signals have to be costly to be honest. For example, among male peacocks, only those of high genetic quality and/or with access to good food resources will be able to put a lot of resources into growing a big tail with plenty of eyes to impress females enough to achieve mating. A male in poor body condition would find it too risky to grow an equally spectacular tail because it would lose resistance against parasites or might be easily caught by a predator (Petrie, 1994). The male peacock's tail thus functions as an anatomical handicap, and the costs involved in growing and keeping it make the tail an honest signal of male quality. The handicap principle has become the most widely acknowledged explanation for honesty in signals (Johnstone, 1995).

Figure 1 Two cleaner wrasses, *Labroides dimidiatus*, inspecting a potato grouper, *Epinephelus tukula*. The open mouth of the grouper signals the 'wish' to have the mouth inspected for the removal of parasites and food leftovers.

Deception and Tactical Deception

Animals often try to deceive other individuals (see some examples below). So how does this fact influence receiver behavior? Particularly in conflict situations, the solution is that everybody tries to cheat as much as possible, but the signals still reveal important information as the possible amount of cheating is physically constrained. Fish erect their fins to appear larger than they are to impress opponents by size, and birds and mammals spread their plumage or fur for the same reasons. The apparent size is nevertheless constrained by the real size, so animals can still assess relative sizes when matching for a conflict. Similarly, body size may constrain the production of low-frequency calls, and a small individual therefore cannot pretend to be bigger than it really is.

The observation that animals may be able to produce signals out of context, eliciting context-specific responses from receivers to their own benefit and to the receiver's cost, has attracted particular attention. Such an ability fits the functional definition of tactical deception (Hauser, 1998). Tactical deception in humans implies high cognitive abilities, such as planning, insight, and theory of mind, and evolutionary psychologists have tried to link tactical deception in animals, particularly primates, to the same mechanisms (Byrne and Whiten, 1988). However, the phenomenon can be produced with a relatively simple mechanism: operant conditioning (Heyes, 1998). All that is needed is that an initial error gets rewarded to start the story. For example, an individual may give an alarm call but immediately realize that it has made an error. However, as everybody else gets distracted, the individual may get increased access to a food source (the reward) and hence associate the alarm call with a food reward. Further studies are needed to find out what mechanisms underlie functional tactical deception in different animal species. Currently, there is evidence for functional tactical deception in mammals (Byrne and Whiten, 1988), birds (Munn, 1986), and fish (Bshary, 2002).

How frequently deceptive signals can be produced so that they still fool observers has to be evaluated. While verbal arguments have predicted low frequencies (Dawkins and Krebs, 1978), game theory models indicate that that is not necessarily the case (Johnstone and Grafen, 1993; Szamado, 2000). In particular, if the benefits of reacting appropriately to an honest signal largely outweigh the cost of reacting inappropriately to a cheating signal, tactical deception may occur at pretty high frequencies. Predator calls are again a good example: rather respond too often to a false alarm and miss out on foraging opportunities than ignore an alarm call when a predator attacks.

Signaling in Communication Networks

Communication often takes places not just between signaler and receiver but in a communication network (McGregor, 1993): bystanders may eavesdrop on the communication and extract valuable information about the participants (aggressiveness, fighting ability, cooperative tendencies, etc.). This fact may have important implications for the honesty of signals. Rather than just trying to optimize payoffs in their current interaction, individuals have to adjust their behavior according to its consequences on future interactions with eavesdroppers (Dutreland *et al.*, 2001; Bshary, 2002). As a consequence, individuals may be more aggressive in agonistic situations to deter potential future opponents (Johnstone, 2001). Eavesdropping may also open up new possibilities for tactical deception. For example, individuals could cooperate or be altruistic in the presence of eavesdroppers to gain a positive image. Eavesdroppers may then seek cooperative interactions with them but will be exploited as the 'deceivers' switch to cheating. This pattern has been observed in cleaning mutualisms where cleaner fish cooperate with small clients to attract bigger clients that the cleaner will cheat by feeding on mucus rather than removing ectoparasites (Bshary, 2002).

A New Element: Costs to the Receiver to Evaluate Signal Information

An interesting question is why humans often tell the truth, given that language is so prone to giving false information, as words are virtually cost free to produce: saying 'I am very rich' takes as much effort as saying 'I am currently unemployed.' There are certainly several components that promote honest signaling. Humans typically interact over long time periods and have very good memories. Hence, they may remember very well if someone cheated them and hold grudges for long time periods. A very interesting component has recently been modeled by Koops (2004). Often, the receiver may not be able to decode a signal without incurring some costs. For example, an alarm call may be without much value as long as the receiver does not know where the predator is. So the receiver has to put in some effort to find this additional important information himself. The more effort the receiver has to put in to achieve relevant information in addition to a signal, the more valuable

the signal must be so that it still pays receivers to listen. As a consequence, signals have to become more reliable the more effort it takes the receiver to decode the signal or to add additional information. A particular feature about humans might be that we tend to verify plenty of information that is given so cheaply by signalers. This effort has two consequences. First, we might find out at some point whether a signaler was lying to us and take appropriate action (usually to the disadvantage of the cheater). Second, we might stop decoding signals if the signal quality is expected to be poor or unreliable. Both consequences promote honesty in signals that are more or less cost free to produce.

Animal Communication: Dialogues

M Naguib, Universitat Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Animals, like humans, often use signals to interact with each other in a dialogue-like manner. Dialogues in animal communication, like in human communication, are signaling interactions in which two individuals take turn in signaling. Such dialogues are most evident in acoustic communication systems, but many of the conspicuous visual displays in contests or mate acquisition also can be viewed as dialogues. Dialogues in animal communication systems can vary enormously in the degrees of freedom with respect to the signaling reply a signal elicits. In the simplest form, a reply to signal A will always be a specific signal, such as A′ or B, i.e., a very stereotyped form of a 'dialogue' with degrees of freedom restricted to minor variation in signal structure and to the temporal relation between the signals. Such

the signal must be so that it still pays receivers to listen. As a consequence, signals have to become more reliable the more effort it takes the receiver to decode the signal or to add additional information. A particular feature about humans might be that we tend to verify plenty of information that is given so cheaply by signalers. This effort has two consequences. First, we might find out at some point whether a signaler was lying to us and take appropriate action (usually to the disadvantage of the cheater). Second, we might stop decoding signals if the signal quality is expected to be poor or unreliable. Both consequences promote honesty in signals that are more or less cost free to produce.

Animal Communication: Dialogues

M Naguib, Universitat Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Animals, like humans, often use signals to interact with each other in a dialogue-like manner. Dialogues in animal communication, like in human communication, are signaling interactions in which two individuals take turn in signaling. Such dialogues are most evident in acoustic communication systems, but many of the conspicuous visual displays in contests or mate acquisition also can be viewed as dialogues. Dialogues in animal communication systems can vary enormously in the degrees of freedom with respect to the signaling reply a signal elicits. In the simplest form, a reply to signal A will always be a specific signal, such as A′ or B, i.e., a very stereotyped form of a 'dialogue' with degrees of freedom restricted to minor variation in signal structure and to the temporal relation between the signals. Such

dialogue forms are typical in insects and frogs or toads, whose complete vocal repertoire is made up of either a single signal or a few signals, and in some dueting bird species, in which the signals of two singers (usually a paired male–female dyad) follow each other in a fixed sequence. In species with more elaborate vocal repertoires, such as in many songbirds and marine mammals, the choice of replies to a specific signal is much larger so that dialogues are characterized by a high dynamic to the time and pattern relations between a signal and its reply. These complex interactions fit best the complex dialogues in human communication, which are characterized by high flexibility in use of vocalizations as replies and counterreplies. In particular, birdsong has become a key biological system to study and reveal the principles of vocal interactions. Similar patterns of communication are now evident in marine mammals, but interestingly much less so in most nonhuman primates.

Many birds and marine mammals are outstanding in the versatility and flexibility with which they interactively use vocal signals. Individuals might answer each other with the same signal pattern, called signal matching, which has been shown to be common in some marine mammals and birds. The signals concurrently may have specific time relations, which is another means of addressing another individual and of signaling motivation – e.g., overlapping the signal of the other animal often is used as and perceived as a form of aggression. Male territorial songbirds use their songs to interact with territorial neighbors, a striking phenomenon that can be observed easily in spring, when singing activity peaks. The frequent countersinging between two or more neighboring males can be highly complex, with high versatility in how songs from the interactants relate to each other. These complex and flexible interactions are probably the best comparison to dialogues in human language. During these dialogues, individuals negotiate about access over resources by signaling their quality, signal their motivation to escalate, or transmit other aspects of their individual states. Often more than two individuals interact in a communication network, but the nature of possible dialogues within such complex settings remains to be shown. The situation is altogether different in another vocally outstanding group of birds, the duet singers, which are frequently found in the tropics. Males and females coordinate their song patterns with astoundingly high precision. The function of these duets can be manifold, and many hypotheses – including cooperative and competitive functions – have been put forward to explain this vocal behavior.

Taken together, vocal interactions in animal communication are strikingly diverse, ranging from very simple forms of signal exchanges to highly complex and dynamic vocal signaling interactions. The functions commonly are related to competition over resources, such as food, space, or mates, but it also appears that specific forms of dueting are associated with cooperative aspects, such as the maintenance of group cohesion and the strengthening of pair bonds. In all these cases, signal patterns emitted by two individuals also have clear relations to each other in the way they are timed. Information content is varied by the use of specific signal patterns and their temporal relation to those of the counterpart. Thus, even though the nature of information in human dialogues differs from that in dialogues in animals, they do share basic principles, suggesting that dialogues have a long evolutionary history and central biological importance in communication and language evolution.

Animal Communication: Long-Distance Signaling

H Slabbekoorn, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Many animals communicate acoustically, without words or syntax. A solitary male gorilla (*Gorilla gorilla*) in Cameroon once shouted at me from approximately 90 m away (see **Figure 1A**). His message, the presence of an impressive creature that did not like me there, was well received. Additionally, I figured out the species and the sex of the animal without seeing it, and (to my relief) I could also tell by the acoustic change in subsequent calls that it was moving away from me. Animals familiar to their habitat and perceptually tuned into the details of conspecific signals potentially pick up even more information. Monkeys and birds, for example, are known to detect and respond appropriately to acoustic cues related to social status, motivation to fight or to have sex, and group or individual identity (e.g., Cheney and Seyfarth, 1990; Collins, 2004). Although the gorilla had been loud and impressive at a relatively short distance, none of the other researchers in the area had noticed his calls: the sound had been unable to penetrate the dense forest very far.

Constrained by the Environment

Animals that use sound to communicate over long distances often try to convey a message that is related to reproduction. Howling monkeys, singing birds, and calling frogs are all usually trying to attract potential mates or deter mating competitors. Reasons for this are that sound can be relatively easy to produce, can be switched on and off, and often works

Figure 1 Acoustic signal design for six animal species, sonographically displayed with time on the *x*-axis, frequency on the *y*-axis, and the relative amplitude reflected in the darkness of the signal trace. (A) Gorilla shout, a very loud sound but the noisy structure with energy spread over a broad frequency range makes it not very suitable for long-distance transmission through dense rainforest (recording contains two shouts plus echo). (B) Winter wren song notes, with a relatively high and wide frequency range; heavy degradation with transmission limits information transfer but allows ranging; estimation of distance to the sound source (recording is a full song without much degradation). (C) Elephant rumble, very low and loud, including sound inaudible to humans (infrasound) and a seismic component, the ultimate long-distance signal (the audible part of the recording is best listened to with headphones on). (D) Green hylia song, two simple notes at one pitch avoiding problems of spectral degradation and exploiting the benefits of reverberations (recording is filtered, which eliminated ambient noise). (E) Tree-hole frog call, with its spectral distribution adjusted to exploit burrow resonance effects (recording has a natural longer interval between subsequent calls compared to the sonogram). (F) Black-backed woodpecker (*Picoides arcticus*) drum, generated using a tree as instrument.

Many animals communicate acoustically, without words or syntax. A solitary male gorilla (*Gorilla gorilla*) in Cameroon once shouted at me from approximately 90 m away (see Figure 1A). His message, the presence of an impressive creature that did not like me there, was well received. Additionally, I figured out the species and the sex of the animal without seeing it, and (to my relief) I could also tell by the acoustic change in subsequent calls that it was moving away from me. Animals familiar to their habitat and perceptually tuned into the details of conspecific signals potentially pick up even more information. Monkeys and birds, for example, are known to detect and respond appropriately to acoustic cues related to social status, motivation to fight or to have sex, and group or individual identity (e.g., Cheney and Seyfarth, 1990; Collins, 2004). Although the gorilla had been loud and impressive at a relatively short distance, none of the other researchers in the area had noticed his calls: the sound had been unable to penetrate the dense forest very far.

Constrained by the Environment

Animals that use sound to communicate over long distances often try to convey a message that is related to reproduction. Howling monkeys, singing birds, and calling frogs are all usually trying to attract potential mates or deter mating competitors. Reasons for this are that sound can be relatively easy to produce, can be switched on and off, and often works

better to reach other individuals than visual and chemical stimuli. Furthermore, sound can convey messages through vegetation, in the dark, and around corners. However, acoustic signals also have their limitations: when traveling from sender to potential receivers, acoustic signals lose energy and the original acoustic fine structure becomes distorted. In short, successful detection and recognition over a long distance depend on the amplitude of the signal as produced by the sender, the auditory sensitivity for the signal characteristics of the receiver, the amount of interference by ambient noise at the receiver, and the level of attenuation and degradation that accrues during transmission through the environment (Brenowitz, 1982; Wiley and Richards, 1982; Slabbekoorn, 2004). This implies that communication potential varies dramatically among animal species, because the transmission distance of successfully conveyed messages heavily depends on body characteristics that allow production of loud sounds, and on the typical environment in which a species lives.

A case study on a tiny bird like the winter wren (*Troglodytes troglodytes*) has shown that its song of many distinct clear notes spread over a relatively wide frequency range (see Figure 1B) indeed suffers dramatically during transmission through their usual habitat with dense vegetation (Holland *et al.*, 1998). Many scattered echoes result in reverberations producing a 'tail' of sound, thereby filling originally silent pauses and masking subsequent notes. Reverberations alter the original temporal and amplitude modulation pattern and together with frequency-dependent attenuation this may render the wren songs difficult to decode. However, there are several ways in which signal and signaling behavior may evolve to counteract such challenging habitat conditions. Winter wrens are exemplary for having a very loud song despite their relatively small body size of approximately 10 g. They are also known to climb up in the shrubs when producing or hearing song and this affects potential communication distance positively by preventing ground absorption as well as high attenuation and degradation rates in usually dense low leaf layers (Mathevon *et al.*, 1996). Interestingly, birds, like humans, are able to estimate the distance of a singing conspecific based on the predictable pattern of degradation and attenuation with transmission distance (Naguib and Wiley, 2001). Thus, on the one hand, signal distortion inevitably leads to information loss, but at the same time several counterstrategies may help animals to cope and the distortion level itself may even provide information of another kind.

Shaped by the Environment

Environments vary in both noise interference patterns and sound transmission characteristics: it makes a difference whether you signal acoustically in a silent and tree-less desert or a noisy and densely foliated rainforest. Given a certain environment, however, the acoustic design of the signal itself also affects effective communication distance. The signal design may therefore evolve to fit local conditions best as another counterstrategy for coping with the environmental constraints. The environment may be noisier in one part of the spectrum than another and there are several examples of animal species that utter their signals exactly within a relatively silent frequency range. The calls of pygmy marmosets (*Cebuella pygmaea*), for example, have frequencies that coincide with relatively quiet spectral regions in the ambient noise of the Amazonian rain forest in Ecuador (De la Torre and Snowdon, 2002). Coqui frogs (*Eleutherodactylus coqui*) of Puerto Rica call within a relatively narrow frequency channel, which is different from those used by other noisy and closely related species in the same forest. In this way, the chorusing males of a diverse frog community avoid interference, with each species tuning into a 'private' frequency channel (Narins, 1995). Recently, a common urban songbird, the great tit (*Parus major*), was found to leave out low-frequency song components in territories with a great deal of low-pitched traffic noise (Slabbekoorn and Peet, 2003). Apart from ambient noise spectra, low frequencies transmit further than high frequencies and are less affected by vegetation, and rapidly repeated frequency-modulated notes do better than long narrow-band notes in turbulent air of open space (Brown and Handford, 2002). As a consequence of all these factors, habitat-dependent acoustics are partly responsible for the evolutionary shaping of the signals present in a particular habitat. Consistent acoustic variation associated with habitat type is found especially in birds and, for example, stereotypically low and slow bird songs are well known to be widespread in dense tropical forests across avian taxa and across continents (Slabbekoorn *et al.*, 2002; Slabbekoorn, 2004).

As one needs low pitch to get far and a large instrument to play a low tune, success stories of long-distance transmission typically come from large-bodied animals. Australian cassowaries (*Casuarius casuarius)* are flightless birds of up to 58 kg and they can produce sounds with fundamental frequencies at approximately 20 Hz, which makes them well designed for their dense rainforest habitat (Mack and Jones, 2003). African elephants (*Loxodonta africana*) can

generate rumbles with fundamental frequencies around 10 Hz (see Figure 1C) and under optimal weather conditions they should be able to communicate with such calls over distances of 10 km or more (Garstang *et al.*, 1995; Larom *et al.*, 1997). The optimal weather for sound transmission is a relatively cold and humid layer of air near the ground and low wind velocities causing little air turbulence. Interestingly, the extremely low elephant calls may also generate a seismic signal component that travels through the ground and which may be picked up by elephants 2 km away. In bad weather, dry and windy, or wet and noisy, seismic signals could even be more reliable than acoustic signals (O'Connell-Rodwell *et al.*, 2000).

Exploiting the Environment

Many animals use sound signals adapted to put up with suboptimal environmental conditions, but some even exploit acoustical phenomena in their surroundings. The reed warbler (*Acrocephalus scirpaceus*), for example, is a common European songbird and lives among dense stands of reed stalks. Transmission experiments revealed that sound above 6 kHz attenuates very fast, but below 4 kHz it transmits relatively well, and below 2 kHz sound may even attenuate less after transmission through reed compared to transmission through the open (Heuwinkel, 1982). The relatively modest and sometimes even so-called 'negative excess' attenuation for some frequencies may be due to resonance properties of reed stalks. Stalks and surroundings may be set oscillating depending on the pitch, modifying frequency-dependent sound transmission, and thereby favoring the relatively low reed warbler songs. The green hylia (*Hylia prasina*) is another small bird beaming its territorial song through dense layers of leaves and twigs in rainforest of Central Africa (Slabbekoorn *et al.*, 2002). Unlike most acoustic designs, its two-note song that remains at the same pitch of approximately 4 kHz (see Figure 1D) hardly suffers from the dramatic reverberations in this habitat. No spectral degradation occurs as all echoes remain at the same frequency, and the temporal pattern is affected by the accumulation of echoes in such a way that it makes the notes longer and louder. So, in contrast to the complex winter wren song, the simple hylia song may actually benefit from reverberations. Playbacks with experimentally manipulated note durations have confirmed that longer notes lead to stronger responses by green hylia territory holders (Slabbekoorn *et al.*, 2002).

The position of signaling individuals within their habitat can be crucial for efficient communication as mentioned above for the wren. This may be especially true for small animals like frogs, for which call radiation has been shown to benefit from sitting on large leaves (Wells and Schwartz, 1982). Similarly, many frog species call from a hole or burrow where they benefit from wall reflections and resonance amplification. Bornean tree-hole frogs (*Metaphrynella sundana*) call from tree holes containing water (see Figure 1E). These egg-deposition sites vary in depth and water level, and the male frogs seem to actively match their call pitch to the associated variation in resonance frequencies (Lardner and bin Lakim, 2002). Burrow resonance can amplify outgoing as well as incoming calls. The call amplitude of a South American frog species (*Eusophus emiliopugini*) was found to be strongly affected by this phenomenon: calls of neighbors were considerably louder inside the burrow of a receiving frog than levels just outside the burrow (Penna and Solis, 1996).

Woodpeckers are also well known to exploit acoustic phenomena in their environment. They advertise their territory by drumming through rapid series of strikes with their bill against a part of a tree (see Figure 1F). Species vary in the rate of strikes, the duration of a series, and in whether rates incline or decline over the series. Consequently, many species can be distinguished by the human ear, and as shown for North American species, together with nonoverlapping distributions and seasonally shifted drumming activity, confusion about drummer identity among woodpeckers themselves is very unlikely (Dodenhoff *et al.*, 2001). The sound spectrum and amplitude level of woodpecker drums are both dependent on the substrate chosen. A study on drumming in yellow-bellied sapsuckers (*Sphyrapicus varius*), using an artificial drumming device to investigate substrate characteristics, showed that the substrate selected for drumming produced louder sounds than nearby sites on the same or different trees (Eberhardt, 1997). Not only woodpeckers use drumming to generate long-distance signals. Chimpanzees (*Pan troglodytes*) are also known to use drumming to communicate over at least a kilometer in their forested habitat, hitting buttresses of trees with hand and feet in combination with vocal 'pant hoot' calls (Arcadi *et al.*, 1998). Furthermore, a variety of smaller mammals 'foot drum' or 'head bang' to communicate with seismic signals; likely, the best option for communication with subterranean lifestyles (for a review see Randall, 2001).

Long-Distance Communication in Humans

I hope it has become clear from the above that many animals that exchange important messages acoustically over relatively long distances are constrained

by their environment. As conveying a message successfully can have important fitness consequences, habitat-dependent sound transmission can direct the evolution of animal signals. Therefore, specific environmental conditions can often at least partly explain the acoustic design of long-distance calls and some animal species have evolved some smart solutions to optimize transmission.

People are also known to use drumming on hollow logs to communicate over long distances though forest or over the African savanna. Furthermore, several human cultures use special whistle repertoires to communicate in montane areas, where walking distances between hilltops can be long, whereas sound can travel as the crow flies (Busnel and Classe, 1976). The acoustic design of these whistles, very similar to the green hylia song, is well adapted for long-distance transmission and may reach others up to 5 km away. However, are any of the phenomena discussed for animal signals relevant to the human voice when used to communicate outdoors? Is the acoustic structure of human language affected by environmental conditions? Interestingly, a comparative study of indigenous languages across the world found a strong correlation between climate and some acoustic features that affect audibility over a distance (Fought *et al.*, 2004). Languages spoken in warm climate zones were shown to have higher sonority levels compared to languages from cold climate zones. Sonority level is determined by the nature and rate of occurrence of phonetic segments and typical consonant-to-vowel ratios. One explanation for the correlation between climate and sonority level may be that depending on climate, people may talk more or less often over a relatively large distance while being outdoors (Fought *et al.*, 2004). Languages with a low sonority score, such as English, must be spoken louder to be audible at the same distance as, for example, highly sonorous Tongan (Nettle, 1994) and these are typical examples from a relatively cold and a warm climate.

Long-distance communication in humans without real words is known from cow- and goat-herding cultures in montane areas. Scandinavian women traditionally use a specific calling technique called 'kulning,' whereas both men and women are known to 'yodel' to communicate among widely dispersed herders in the Alps. Kulning can be described as a kind of loud singing of relatively high-pitched tones, produced with unusually high subglottal pressure and lip, mouth, and throat adjustments for optimal use of vocal tract resonance or formants (Tellenbach Uttman, 2002). The reason for an incline in frequency associated with an effort to become loud (see, e.g., Vilkman *et al.*, 2002) may be that it is easier to produce a higher tone at a high amplitude, but it may also exploit best transmission channels for a target distance, or avoid masking by the usually low-pitched ambient noise of rumbling wind and mountain streams. Yodels are also relatively high and the typically repeated alternation between normal chest voice and head voice or falsetto may also have evolved through proven efficiency in long-distance detection and recognition. Abrupt frequency changes are very common in animal long-distance calls and are, for example, known to convey important information in doves. Whether the outcome of call evolution in humans communicating through forest would yield exactly the same acoustic design as found in open areas is not clear, but Tarzan's well-known long-distance call is technically also a yodel and must have reached much further than the wide-band noisy calls of his gorilla friends.

Acknowledgment

While writing this article, I was supported by the Netherlands Foundation for Scientific Research (NWO-PULS grant: ALW 831.48.006). I would like to thank Danielle Dodenhoff, Björn Lardner, Anna Nousek, and Caitlin O'Connell-Rodwell for the kind permission to use their recordings, and Donald Miller, Thijs Schrama, and Johan Sundberg for references and stimulating discussions.

Animal Communication: Overview

M Naguib, University of Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Animals, like humans, communicate with one another, often in strikingly complex ways. Despite obvious differences between human communication and communication in animals, there are many fundamental similarities in the underlying principles. Anticipating how and why animals communicate makes an important comparison to human communication and provides a broader background for understanding human speech and language. Communication in animals and humans has a shared evolutionary history and thus understanding animal communication also helps to elucidate the biological basis of human language. Communication in animals has deep implications for their social life, survival, and fitness; thus,

communication systems are among the key research models to elucidate biological processes from within a mechanistic and an evolutionary perspective. It allows the integration of questions raised in, for instance, psychology and very different biological fields, including physiology, neurobiology, genetics, development, and cognition as well as population biology and evolution. Communication, in general, is one of the most fundamental issues in life, as it is crucial at all organismal levels. Cells must communicate within an organism and there are specific adaptations for signals, such as hormones and transmitters, that act as information carriers at these levels. When talking about animal communication, however, we refer to communication among individuals, which is the topic of this article.

Definitions

In many cases such as the melodious song of songbirds and whales and the fascinating body patterns and color traits that are displayed during social interactions, it is undebated that animals communicate. However, there are cases such as a mouse rustling in the leaves and by this behavior attracting a predator that we generally do not interpret as meaning that the mouse is communicating with the predator despite influencing its behavior. For such cases, definitions are helpful and necessary to set the stage even though one must keep in mind that there are numerous definitions that differ in subtleties and in their focus and that it is more important to deal with the issues and questions of interest rather than with coarse definitions. The most common and most widely accepted definition is that animal communication is behavior involving signals as information carriers. Signals in animal communication are understood as behaviors or traits that have evolved **specifically** to provide information from a sender to one or more receivers. Thus, birdsong or frog calls are signals, whereas coughing is not a signal (unless it becomes ritualized to act as signal) even though it provides information about the signaler (e.g., possibly its health status). If information is derived from traits that are not signals, these traits are usually referred to as cues. Signals also cause a change in the state of the receivers without providing the physical energy for this change, another definition that is frequently used. Pushing someone off a cliff is not a signal; telling him or her to jump off is a signal. The nature of a specific communication system then is characterized by a broad range of factors, such as the species, the social system and context in which communication takes place, the function of signals, the interests by senders and receivers (which commonly differ between them), and the sensory modalities used as well as the abilities to produce signals and to perceive and to process them.

What Is Communicated

One of the central questions in animal communication is related to the information that is communicated. Animals communicate information often by using complex signals that simultaneously carry different kinds of information or by using compound signals that carry information in several sensory modalities. In general, animals communicate information about themselves, such as their individuality, species and population identity, age, motivation, genetic background, developmental history, physiological condition, and intentions. In contrast, evidence that animals communicate about external events (referential signaling) is limited to some very specific cases. The best evidence that animals use referential signals comes from honeybees (*Apis melifera*), presumably the most famous case, where the waggle dance on the hive provides information to group members about the location and direction of a food source. Also, alarm and warning calls by birds and primates have been shown to be functionally referential, i.e., that specific signals are used in response to specific types of predators. In general, when dealing with communication, the message, as coded by a sender, must be distinguished from the meaning, as decoded by a receiver, of a signal. A sender codes information in a signal and the signal as information carrier then will carry this information as a specific message. The meaning of a signal, however, depends not only on the sender and the coded information but also on the receiver. For different receivers, a signal that carries the same message may have a different meaning, or even no meaning at all (**Figure 1**).

An advertisement signal by a male may attract a female, as the meaning to a female may be *I am a high-quality and attractive male*, whereas the same signal with the same message may mean to a rival male *I'd better stay away as this is a strong male* and to an individual of a different species that signal may have no meaning at all.

Sensory Modalities

Animals have evolved an enormous variety of highly specialized communication systems across all sensory modalities, such as acoustic signals, visual signals, chemical signals, electric signals, and tactile signals. Each sensory modality has its own advantages and disadvantages in information transfer and there are many intrinsic and extrinsic factors that have favored and shaped the particular communication system in a

Figure 1 Schematic illustration of the message and the meaning of a signal. A visual or acoustic signal by a sender (center) contains a message to its conspecifics. For a rival male (bottom right), the meaning will be different than for a female (top left). Rivals may be repelled by the signal, whereas females may be attracted. The message is not directed at individuals of other species and may have no meaning to such an individual (bottom left). However, even though the signals and its message are not directed at individuals of other species, the signal may have meaning to a predator that uses such a signal to localize its prey. Drawn after Slater (1999), *Essentials in Animal Behaviour*, Cambridge University Press, Cambridge.

given sensory modality within a species. Among these factors, there are phylogenetic and morphological constraints, and constraints imposed by the environment through which the signals must travel from a sender to a receiver. Which sensory modality is used obviously also depends on the kind of information that is signaled and its biological significance. Advertisement signals for mate attraction need to transmit far and omnidirectionally, e.g., acoustic signals. They also need to be conspicuous, e.g., acoustic signals or visual signals when the habitat does not constrain sight; signals need to be persistent, even in the absence of the sender, e.g., chemical signals used in many mammals for territorial marking. Short-range interactions, such as communication between close group members or parent–offspring communication during feeding or nursing, require a different set of signals that often are soft and subtle. Many of the basic principles of communication apply in one form or another to several sensory modalities. For those interested in language and linguistics, vocal communication presumably will be of most interest. Thus, this article, in addition to focusing on general issues and providing an overview about the three best studied sensory modalities, draws several examples from vocal communication as well because it provides key examples of major issues in animal communication. Despite separate treatment of the sensory channels, it should be mentioned that often communication involves a

Figure 2 Communication often involves concurrent and compound signaling in different sensory modalities, as in these common gulls, in which calling is associated with specific body postures.

simultaneous combination of different modalities (Figure 2).

Acoustic Communication

Acoustic communication is found across the animal kingdom and in most cases is characterized by its conspicuousness, even though acoustic signals can also be subtle and soft. Some animals even communicate acoustically outside our hearing range, such as bats or rats, which use ultrasound, or elephants, which communicate in the infrasonic range. Birds and whales sing, frogs and insects call, deer roar, and there are many other examples making us wonder what the functions of these complex and diverse behaviors are. In most cases, the loud and conspicuous signals are advertisement signals used for resource defense, such as a food source or a nesting place, or to attract a social mate or a mate for extrapair copulations. Acoustic signals are ideal for such advertisement as they allow rapid coding of complex information and most importantly the signal with its information transmits almost omnidirectionally. Thus, acoustic communication is less 'private' than visual or even tactile communication, as in most cases the signal cannot be sent exclusively to a specific receiver. In long-range communication, which often occurs over distances of 100 m or more in birds or even occurs over distances of kilometers in whales or elephants, the signals degrade and attenuate over a distance, leading to signals being different in structure at the position at which a receiver makes a decision compared to the signal structure at the source. Thus, the information available to a receiver, the transmitted information, can differ from the coded information, an issue of increasing interest in studies on animal acoustic communication. Selection by conspecific receivers has led to signals being adapted to the acoustic properties of the habitat by favoring lower frequencies and slower repetition rates of similar

Figure 3 Sound spectrograms of alarm calls of five different species of European songbirds. Calls are very similar in structure. Due to the narrow frequency bandwidth and the lack of strong frequency modulation, the caller will be difficult to localize by a predator. High frequencies also do not travel very far so that they are well suited to warn nearby conspecifics without alerting distant predators. Drawn after Slater (1999), after original source in Thorpe (1961), *Bird song*, London: Cambridge University Press.

Figure 4 Differences in the hearing curves of great tits and sparrow hawks. The lines above the *x*-axis indicate that the hearing of great tits is superior to that of a sparrow hawk. The alarm calls are centered in the frequency range where hearing by great tits and other songbirds is most superior to that of sparrow hawks. Thus, the high pitch is well adapted to warn nearby conspecifics by minimizing the risk of being heard by a predator. Drawn after Klump *et al.* (1986), *Behavioural Ecology and Sociobiology* 18, 317–323.

frequencies in closed habitats that lead to strong attenuation and reverberation compared to those of signals of species that settle in open fields. Such adaptations reduce ambiguities and increase the efficiency of communication over long distances. Striking examples of adaptations of acoustic signals to the acoustic properties of the environment and receivers' hearing and perception are the high-pitched 'seep' alarm calls given by many songbirds in response to predators (Figure 3). The lack of strong frequency modulation makes the signal difficult to localize and as high-pitched sounds they do not transmit far and thus the sender avoids the risk of being heard and attacked by a predator while still warning nearby group members. A classic study on this topic has shown that songbirds hear significantly better in the frequency range of these calls than do predators (Figure 4).

In addition to alarm calls and advertisement signals, there are many other, often subtle, vocal signals, such as contact calls, food calls, or begging calls.

For those interested in language and linguistics, it is of particular interest that acoustic signals make the best and most direct comparison to human language. Like human language, acoustic signals permit rapid coding of information and thus varying information content rapidly over time. Most interestingly, acoustic communication systems in some animals bear striking similarities to human language even though this may not be evident at first sight. Birdsong makes the best comparison. Like language, it develops under the influences of vocal learning with a key sensory period early in life and it requires a period of vocal practice. There is striking geographic variation, even with discrete dialect boundaries, similar to that which occurs in human language. Birdsong is also learned without specific instruction being required and on a neurobiological level, song is controlled by specific brain regions that are lateralized, as is known for the regions for speech production and comprehension. Birds, like humans, even assess the distance to a source of sound using the same set of cues provided by environmental attenuation and degradation resulting from sound propagation.

Visual Communication

As in humans, vision in general is a key sensory modality in the behavior of many species so that communication is also of central importance in this sensory modality. Transmission distance and direction of visual signals obviously depend on the structure of the habitat. In dense vegetation, such signals are suitable only for short-range communication, whereas in open habitats, they may well be used for long-range communication, even though communication distance in general will be shorter than if using acoustic signals. Visual signals also are more directional than acoustic signals so that they are well suited to address a specific individual but are less well suited to general

omnidirectional advertisement. Two kinds of visual signals need to be distinguished: Those that are always 'on' and those that can be turned 'on' and 'off' like acoustic signals. Visual signals that are always on, such as specific body coloration, allow the individuals to signal continuously with these markings without making a specific active signaling investment in addition to having produced the signal and maintaining it. Such signals that are always on are thus not suitable for transmitting information about any aspect of an individual that varies on a short time scale, such as motivational aspects of behavior. Well-known examples of such visual signals are fur marks in mammals, colorful feather ornaments in birds, and antlers in deer. Other kinds of visual signals can be turned on or off and such signals are visual displays, such as the waggle dance in bees, the zigzag mating display in sticklebacks, and the peacock's train. Such visual behavioral displays in which specific body postures are used to transmit information, or in which specific color or body patterns are displayed actively, can be used to signal additional information that varies on a short time-scale, i.e., motivational aspects of behavior, as the peacock does with its train or some butterflies do by opening their wings when detected by a predator. The information transmitted by visual signals can be directed more specifically at certain receivers. Such directional signaling can be advantageous as it reduces the probability that unintended receivers intercept and extract information that is not in the sender's interest. In addition, directed signaling can attract and maintain attention by intended receivers, leading to specific signaling interactions as is well known for the classic example of mating displays in sticklebacks. Of course, acoustic signals also can be used to specifically address an individual but here it is more difficult to exclude other individuals from receiving the signal. Visual signals may code information about the nutritional state of an individual when the colors or metabolic precursors that are deposited in the fur or the feathers are not easily obtained. Visual signals also may reveal information about age, such as antlers in deer, or developmental history, as has been reported for symmetric ornaments, such as tail streamers in birds. Such signals may be used in decisions on mate choice as they are linked to current nutrition or the nutritional history during development, revealing honest information about aspects of an individual's quality.

Olfactory Communication

Olfactory signals are widespread in the animal kingdom. Even though they are generally less variable and complex than acoustic and visual signals, there are situations in which the use of olfactory signals is advantageous to the signaler. Olfactory signals that are produced specifically to provide information to other individuals are called pheromones but animals can also obtain information about other individuals by perceiving odors from body glands or urine that are not classified as pheromones. Olfactory signals have the major advantage over other signaling modalities in that they can be present even when the sender is absent. Thus, they seem to be ideal for marking territories or home ranges that are too large to be patrolled continuously. Many mammals have specific glands to produce pheromones that they deposit on the vegetation to mark a site as being part of their home range or territory. Compared to acoustic and visual signaling, such marking is considerably cheaper in terms of the energy invested, both in producing the signal and in the time spent signaling. Once the chemical is produced, a persistent pheromone can be used as a marker that is effective for many days and subsequent decay can give a measure of time. Acoustic signals and visual displays, in contrast, require continued signaling and thus are time- and energy-consuming. Furthermore, olfactory signals are important in mating decisions as females can signal their receptivity to males and recent research has shown that olfactory signals are used to assess genetic similarity on which decisions on mate choice are based. Chemical signals that are not deposited on vegetation or on the ground may be released into the air and attract mates. One of the most striking examples here is the wax moth, which releases a pheromone called bombycol, even single molecules of which can be detected by males. Thus, even though chemical signals do not permit coding of highly complex information that can vary rapidly over time, as is the case for acoustic signals and visual displays, they are an important sensory modality for communication in certain contexts.

Cognition and Communication

Cognitive capabilities in communication are among the most fascinating areas in animal communication. The complexity of animal signaling and the range of response strategies to signals clearly show striking cognitive capabilities in animals. Famous examples are the comprehensive capabilities of apes, dolphins, and parrots when being trained with sign language or spoken language. Animals possibly withhold information and may use signals to mislead others, which requires complex information processing that goes far beyond simple stimulus–response systems, as animal communication sometimes was seen in early psychological studies. Animals must continuously update their information about their social environment

and by doing so memory also plays a key role. The information that an animal extracts from a signal then may be processed by integrating it with previous information to even generate specific expectations about future communication events. Recent studies have shown that animals often establish communication networks in which they not only extract information from single signals directed to them but also through transitive inference extract information by attending to others' interactions (eavesdroppers). Combining their own information obtained through signaling interactions with information obtained by observing signaling interactions among others requires a sophisticated system of information processing. In social animals, individual recognition on the basis of signals often is fundamental to enable complex relations and again there is evidence that long-term memory is involved, so that animals remember specific individuals and their relation to them even after a year or more of separation. Animals also have striking capabilities in production, usage, and comprehension learning of communication signals, and examples again are found in the well-studied songbirds, parrots, and marine mammals.

Cooperation and Deception in Communication

Often, superficial observations of animals and their communication behavior suggest that communication serves to bring about cooperation, for instance, in defending a territory, as duetting bird species do, where males and females jointly sing complex and melodious songs, or in animals where parents communicate in raising their young, or when groups of animals peacefully move along without any form of aggression being noticeable. Such apparent cooperation in reality often involves a strong conflict between the communicating individuals. Individuals often have conflicting interests as selection will favor those individuals that maximize their reproductive fitness. Cooperation thus is stable in those communication systems in which both interacting individuals have a benefit on their own. Males that signal to attract a female benefit by appearing better and more attractive than they are, whereas females benefit by not being fooled and from using honest indicators of male quality in their assessment. Selection by receivers is thus a leading force in making communication systems on average honest as receivers will be selected to not respond to signals carrying false information. However, as with any system of information transmission, there is uncertainty and noise and thus the probability of correctly rejecting a signal with false information must be traded off with the probability of incorrectly rejecting a signal with accurate information. These basic features of signal detection theory open room for error and deception in animal communication.

Costs and Benefits of Signaling

Animal signals can carry substantial costs to a sender. The costs may lie in the energetic or other physiological costs of producing the signals, in the time devoted to signaling, or in the social costs when signals elicit specific responses by other members of the species or even attract predators. There are often conflicting interests in communication between an animal emitting a signal and those animals that are receiving the signal and that must decide whether or not and how to respond. This conflict of interest is especially evident in signals that are used to advertise and defend resources, such as food, space, or mates. Also, in parent–offspring communication, there can be substantial conflict of interest. An individual offspring that begs for food will have a different interest than that of its parents, which must invest time and energy to provision the offspring and may have to feed several offspring at the same time. As a result, selection on signalers in such a case will favor signals that exaggerate the quality or need of the signaler (cheating or deception), whereas selection on receivers will favor them to extract accurate information from the signal about the sender, i.e., not to be cheated. Thus, if signals consistently provide misleading information, receivers should stop responding to such signals. As the effectiveness of a signal will depend on the receiver's response, communication systems at equilibrium are expected to be honest on average but at least some cheating can persist. This principle was first coined by Zahavi (1975) as handicap signaling, which is meant to indicate that receivers should respond only to those signals or signal components that carry costs to the sender. Such costs would ensure honesty as only those individuals in good quality will be able to produce such a signal or only for them it will pay to produce such a signal. There is ample evidence in the animal kingdom that signal expression indeed is costly and is linked to an individual's quality. But it also needs to be noted that not all signals can be viewed as handicaps, in particular when they are cheap to produce and when the cost/benefit ratio of a signal is low.

Functions of Signals

Animals communicate, like humans, in many contexts. Information signaled will be different in different contexts and different contexts also impose

different constraints on information transfer. As a result, signals can differ strikingly depending on the context in which they have evolved. Advertisement signals are loud and conspicuous, whereas other signals may be soft and subtle and thus inherently more difficult to study. The best studied signaling systems in animals are those that are linked to resource defense, such as territorial advertisement; mate attraction; parent–offspring communication; and alarm calling. Signals in these contexts are usually not only of central biological relevance but also are conspicuous, which permits good access for scientific investigations. Apart from the specific context of alarm calling, signals in these contexts contain information about an individual's state, motivation, or quality. Thus, by and large, animals communicate information about themselves and evidence for referential signaling, i.e., signaling about external environmental events, is limited mainly to some specific examples, such as some cases of alarm calling.

Mating Signals

Many of the most conspicuous signals used in animal communication are mating signals, i.e., signals that are used to attract a partner for reproduction. Many of the loud vocal and visual displays found in birds, insects, frogs, toads, and primates are related to mating. In these cases, commonly only the males display and they do so often to attract females and to repel rival males. Also, many color displays, such as feather ornaments in birds or colors in fish, are related to mating contexts. Why have mating signals evolved to be elaborate and conspicuous? First, animals are often spaced far apart so that advertising individuals need to be conspicuous to attract potential mates from a distance. Second, mating and reproduction provide material for natural selection to work on and those individuals that are most successful in reproduction will leave more and often better offspring to the next generation. Individuals, and in particular the males, compete for access to reproduction so that selection should favor those individuals that are most successful in gaining reproductive partners of high quality or in large numbers. Thus, signals that are used to make reproductive decisions should provide information about the quality of the signaler. The resulting sexual selection leads to signals that are largely resistant to cheating, i.e., that do not allow an individual to signal better condition than it actually has. Elaborate signals have been shown often to carry costs in terms of production and maintenance as well as the likelihood of attracting predators. Such costly signals maintain the average honesty of a communication system.

Communication for Defending Resources

A second key issue in animal behavior and thus animal communication is the defense of resources. Key resources are space, such as territories, nesting sites, or food sources (and also mates, as discussed above). In order to defend resources, animals often need to signal aspects of their quality, e.g., fighting ability or resource-holding potential. As the same information is often important in mate choice, in many cases we find signals with dual functions – on the one hand, to serve to attract and maintain mates and, on the other hand, to repel rivals. Within this broad classification of signal functions, there are, however, important subtleties in the use of different signals that are relevant in only one or the other context. A male bird sings to attract a mate and to repel rival males but it then may sing differently depending on which function predominates. It may sing a soft complex song at a slow rate to a female nearby and a loud simple song at a high rate to rivals that threaten the territory. It may sing differently when nondirectionally advertising a territory but suddenly may switch to a very different singing mode with different singing patterns and timing of song once his territory is threatened by a rival. Siamese fighting fish (*Betta splendens*) may use the same signaling behaviors when courting a female as they do when trying to evict a rival. The way the pattern is displayed and integrated with other traits in behavior and communication then affects the value of the signal so that it is effective in either context.

Responses to Predators: Alarm and Mobbing Calls

Many animals produce loud and conspicuous vocalizations when they detect a potential predator. These warning signals can be either alarm calls that are given without approaching the predator (usually such calls are given immediately before a flight response) or so-called mobbing calls, which are used in combination with an approach to a predator. Both kinds of calls are interesting from an information theoretical perspective as they have been used as key models to investigate referential aspects of animal communication. Alarm and mobbing calls usually encode information about the urgency of the situation, such as the kind, threat, or distance of the predator. In addition, there is growing evidence that they are functionally referential, i.e., that specific call types or variants are given with high probability in response to specific predators. The classic example for such predator-specific calling is vervet monkeys, which use different calls in response to different types of predators and which also respond differently to the different calls in adaptive ways to avoid particular types of predators (**Figure 5**).

Figure 5 Alarm calling of vervet monkeys. Different calls (shown as sound spectrograms) are given in response to different predators. Playback studies have shown that the different calls elicit different flight reactions that are adaptive with respect to the type of predator for which the calls are given. Drawn after Slater (1999), *Essentials in Animal Behaviour*, Cambridge University Press, Cambridge.

In vervet monkeys, calls given in response to aerial predators elicit hiding responses, calls given in response to mammalian ground predators, such as leopards, elicit flight up into trees, whereas calls given in response to a snake elicit attention to the ground. In other species that do not have separate flight reactions to different predators, the evidence for functionally referential calls is less clear and current evidence suggests that calls vary with differences in urgency rather than differences in type of predator even though these two possibilities are not fully mutually exclusive.

Studying Animal Communication

The information available about all aspects of animal communication is in part constrained by the techniques that allow us to study these communication systems. Animals cannot be asked directly which information they have coded in a signal and which information they have extracted from a signal so we must rely either on inferences from descriptive studies on animal communication systems or on experiments. From these, we then can obtain insights into the information signaled, received, and evaluated by the animal's behavior under controlled experimental conditions. Depending on the questions involved, data are collected in the field either through observational studies or by conducting field experiments. Laboratory studies in general allow much better control of the context but these studies are often limited by animals not communicating in the laboratory as they would under natural conditions in the field. Laboratory studies using operant conditioning regimes, for instance, are ideal to test 'just noticeable differences' in signal structures, an issue that is important to obtain insights into the perceptual capabilities of animals. Field studies in natural settings, in contrast, test for 'just meaningful differences' in signals or signaling strategies, as animals may respond similarly to signals that they perceive as being different but that still have equal salience to them. Playback techniques using sound, or increasingly also video, have been among the most powerful experimental tools in experimental research on animal communication. Often, animals readily react to such stimuli in a natural manner and by clever experimental designs and manipulation of stimuli, responses of animals to playback reveal insights into the information and its biological value decoded from the signal. The continuous refinement of possibilities to digitally manipulate signals (visual and acoustic) opens up exciting areas for future research, which should allow the unraveling of subtleties in animal communication that in many cases still remain a secret.

Comparison to Human Language

In general, finding a unique and specific difference between communication in humans and animals is not easy. Most of the traits that were believed for decades to be unique to human language have been shown to be part of one or another communication system in animals. Animals may communicate intentionally and they may withhold information on purpose even though these aspects remain difficult to study empirically. They can cheat and mislead one another. Animal signals can provide information about the past (signals reflecting quality) and the future (signals indicating intentions) and be functionally referential (alarm calls). On the other hand, the complexity of message coded in human language and its flexibility clearly go beyond what we know about animal communication. As such, human communication differs from animal communication not so much in specific traits but rather in its complexity and flexibility. Moreover, even though animals have been shown to produce referential signals, i.e., signals that label external objects, the examples are restricted mainly to certain contexts and are of limited

flexibility. A striking aspect is that our closest relatives, the apes, are very restricted in their vocal communication. Their sound repertoire is limited and calls in primates in general are not acquired under the influence of vocal learning as is the case in humans and other animals, such as songbirds or some marine mammals.

Animal Communication: Parent–Offspring

F Trillmich and A Rehling, University of Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Communication between parents and offspring ensures offspring survival, growth, and successful development to independence. Parents invest time and provide food, protection, and – in endothermic organisms – warmth. This costly brood-care behavior can evolve only if the donor obtains fitness benefits for its actions. Such benefits arise if the receivers of parental care share genes with the care-giving individual. Consequently, care should be expended only on own offspring or those of close relatives, and not on unrelated individuals. This is ensured by recognition mechanisms.

Beyond recognition, parental care should be allocated in such a way that the costs incurred lead to maximal benefits (fitness) achieved through offspring. This makes communication about the needs of offspring necessary. However, offspring compete for the limited, precious resource of parental care whether directly with siblings in a brood or indirectly with

flexibility. A striking aspect is that our closest relatives, the apes, are very restricted in their vocal communication. Their sound repertoire is limited and calls in primates in general are not acquired under the influence of vocal learning as is the case in humans and other animals, such as songbirds or some marine mammals.

Animal Communication: Parent–Offspring

F Trillmich and A Rehling, University of Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Communication between parents and offspring ensures offspring survival, growth, and successful development to independence. Parents invest time and provide food, protection, and – in endothermic organisms – warmth. This costly brood-care behavior can evolve only if the donor obtains fitness benefits for its actions. Such benefits arise if the receivers of parental care share genes with the care-giving individual. Consequently, care should be expended only on own offspring or those of close relatives, and not on unrelated individuals. This is ensured by recognition mechanisms.

Beyond recognition, parental care should be allocated in such a way that the costs incurred lead to maximal benefits (fitness) achieved through offspring. This makes communication about the needs of offspring necessary. However, offspring compete for the limited, precious resource of parental care whether directly with siblings in a brood or indirectly with

potential siblings of future broods. In this competitive situation, individual offspring might try through exaggerated signals to manipulate parents into providing more than a just share to the signaling individual. As such an unequal distribution will not be optimal for the parent, conflict might arise about the distribution of care between parent and offspring as well as among siblings and between broods (Mock and Parker, 1997). Conflicts result because selection favors different optima for parent and offspring regarding the extent of brood care due to the asymmetry that parents are equally related to all offspring and potentially gain the same fitness returns via each one of them, whereas offspring are selected to value their own well-being more highly than that of their siblings (Trivers, 1974). Parent–offspring communication therefore takes place in a field of conflicting interests. We here concentrate on parent–offspring communication in birds and mammals. Recognition and communication between parents and offspring in invertebrates are largely based on chemical (and tactile) cues. Readers interested in these communication systems are referred to Hölldobler and Wilson (1990) and Trumbo (1996).

Signaling for Parent–Offspring Recognition

Among species, offspring vary in developmental stage at hatching or birth. Young may be altricial, characterized by complete nutritional and thermoregulatory dependence on parents, closed ears and eyes, and very limited locomotory ability, or they may be precocial, that is, they appear like miniature adults, with much further developed sensory, locomotory, and thermoregulatory abilities than altricial young. Recognition might be based on location if young are immobile as in most altricial birds and mammals. However, individual recognition or recognition of specific social categories is needed with precocial young, which are mobile soon after hatching or birth. Consequently, the probability of errors in identification of own parent or offspring might be high. To achieve recognition, animals use auditory, visual, and chemical cues. Such recognition may be one-sided, parent to offspring, or mutual, between parent and offspring.

As the example of the altricial bank swallow (*Riparia riparia*; Beecher *et al*., 1981) demonstrates, recognition might be based on different cues at different stages in the ontogeny. During the first 15 days, parents use the nest site as a cue to identify their offspring. At this stage, experimental brood exchange causes no disruption of parental care in bird species with altricial young. This leaves parents vulnerable to brood parasitism, be it intraspecific or interspecific, as by cowbirds and cuckoos. Only just before chicks leave the nest, bank swallow parents learn to recognize offspring individually by their begging calls, which develop individual signatures, thus ensuring selective feeding of own offspring after fledging. In bank swallows, recognition errors account for only 0.5% misfeeding of alien young after fledging (Beecher *et al*., 1981).

In high-density colonies of many seabirds, mutual individual recognition is essential from the very beginning. Mutual recognition can become established even before hatching, as in guillemots (*Uria aalge*; Tschanz, 1968), where parents recognize their own eggs by color and pattern. Toward hatching time, parents emit a contact call to which the chick in the egg reacts by uttering sounds. Chicks about to hatch do not react to calls of other adults, demonstrating their ability to recognize parental calls. In the extremely dense colonies of emperor penguins (*Aptenodytes forsteri;* Jouventin *et al*., 1979), parents and chicks memorize their respective calls, which allow individual identification later on. This becomes vital when parents leave the young for extended foraging excursions at sea. A parent arriving back from its foraging trip repeatedly emits the call while wandering through the colony. When the chick recognizes its parent's voice, it vocalizes in response. On reunion, the parent requires the young to vocalize and may run off, forcing the chick into a feeding chase to elicit repeated calling and thereby ensuring that it is feeding its own chick. Only after correct recognition has been firmly established does feeding follow. In a similar manner, vocal recognition combined with strong site fidelity and olfactory confirmation of individual identity ensures mother–offspring recognition in colony-living sea lions and fur seals.

Some mammals give birth to precocial young that are mobile right after birth, for example, horses, sheep, deer, and, among smaller mammals, guinea pigs. In these species, recognition must be established within the first few hours after birth. Recognition can be achieved through chemical labeling by licking and nursing of young after birth. Applying her own chemical label initially helps the mother to distinguish her own offspring from alien young. For chemical cues specific to the offspring, an imprinting-like process in the mother has been documented, for example, in sheep (Lévy *et al*., 1996). Later in the ontogeny, further mechanisms are often added, such as long-distance recognition by voice cues that enable parent and offspring to identify each other. Use of multiple cues might be quite common to ensure proper recognition but has only rarely been demonstrated.

In precocial birds, such as many shorebirds and geese, acoustical cues play the major role in parent–offspring recognition. Long-term bonds may be forged that maintain family cohesion even over periods of long-distance migration in large flocks, for example, in swans and geese, where families migrate together to the winter quarters and may stay together as a family unit until the next breeding season.

Communication in Brood Care Transactions

Quite often, recognition will guide actions much more reliably in parents than in offspring, because the former would incur a major cost if expending care on alien young, whereas offspring might benefit from approaching and inducing parental care in alien parents as long as these do not act dangerously aggressive toward foreign offspring.

In addition to ensuring that parental care is given to their own offspring, parents should be able to adjust their care to the needs of their offspring. Young vary in needs and condition and parents must assess these parameters to provide optimal care. Young should therefore communicate their needs to the parents to extract care. Begging signals potentially convey information about the offspring's immediate needs (hunger) and longer term state (body condition). Parents should act on these signals and communicate the offering of care to offspring. A variety of begging behaviors and offering strategies have evolved to meet these functional demands. Both sides use specific and complex signals in this interchange. Much thought has been given to the question that parent and offspring are under differing selection over the amount and duration of care provided, and the present state of modeling usually assumes that signals of need must be costly to maintain honesty (*see* **Animal Communication: Deception and Honest Signaling**).

Offering Strategies

Special signals evolved to signal the location of the food source in mammals as well as in birds. Lactating rabbits visit the young once per day for a few minutes only. Mothers secrete a special chemical to signal to the young the location of the teats, an absolute necessity in the dark burrow to enable pups to find the teats and suckle during the brief presence of the mother. The chemical signal eliciting this response has been well characterized (Schaal *et al.*, 2003) and was shown to be sufficient and necessary for successful nipple attachment. This chemical (2-methylbut-2-enal) is produced only in the nipple area by nursing females, thus proving its specific signal character. In precocial offspring such as lambs, mothers tend to offer the udder to the offspring by positioning themselves and opening up the access to the udder by moving the leg outward. In many species, such mechanical, chemical, and visual signals might be supported by acoustic signaling. Acoustic signals might also help to attract the offspring's attention and maintain proximity between mother and pup. In pigs, the grunts of the sow signal to her many piglets to gather at the teats to obtain milk at milk ejection. Piglets must be synchronized because milk ejection lasts for only 10–20 s. The sow produces a milk ejection reflex after sufficient stimulation through massage of the teats by the piglets but is unable to nurse again for some time after milk ejection. Similarly, many bird parents announce their arrival at the nest by a call and they touch the young's beak to encourage begging and opening of the mouth. In species with more precocial offspring, such as gulls, parents offer food by bending down to the chick and repeatedly moving the bill in front of them to attract attention. Finally, in independently feeding chicks, such as chicken, mothers point to food items, thus showing the chicks what can be eaten and where to find it.

In bird nests, shuffling to obtain the best position and sometimes violent sibling conflict to keep siblings from competing for food are often noticeable attributes of begging. Surprisingly, parents quite often pay no detectable attention to squabbles and aggressive encounters among chicks but apparently allow sibling competition to run its course even if one or more chicks die in the process. This is particularly surprising when observing the recently hatched cuckoo chick evicting its nest-mates in front of the passively on-looking parent's eyes. Similarly, in some eagles, herons, and boobies, parents may watch one sibling driving off or directly killing another one (see Mock and Parker, 1997 for a review of sibling conflict).

Whereas many parents appear rather passive in their attention to offspring, essentially feeding the one that begs most intensely by calling or stretching its neck highest, in some bird species closer observation has shown that male and female follow different strategies, paying attention to different aspects of chick needs. In the budgerigar, females feed the smallest chick preferentially, whereas the father feeds all chicks indiscriminately. Such favoritism has not been demonstrated in mammals, where mothers may find it more difficult to influence offspring position at suckling. However, in several large mammals, such as red deer (*Cervus elaphus*) and Galápagos fur seals

(*Arctocephalus galapagoensis*), females will aggressively drive off offspring from a previous year once the next offspring is born.

More chronic signals serve to maintain parental care. In the rat, via pup-typical smell and actions such as sucking, pups mediate prolactin release in the mother and thereby keep her in the maternal state so that she is motivated to warm, lick, and nurse young. By repeatedly fostering young pups to a mother, researchers were able to maintain the maternal state inclusive of lactation far beyond normal weaning. Conversely, a mother rat is characterized by an odor that is not specific to the individual but signals maternal state and thereby makes her attractive to pups.

Alarm calls are another important type of signal used by parents to communicate with their offspring. In many species, these calls seem to be recognized from birth. Depending on the state of development of locomotory abilities, young may respond by hiding or quieting immediately, thus reducing the risk of being detected by a predator.

Begging Strategies

Parallel to the provisioning strategies of parents, offspring behaviors that enable the communication of their state have evolved. Newborn young or freshly hatched chicks soon learn to attend to many subtle features of the feeding situation, thereby becoming more and more active participants in the transaction. They communicate their needs by the intensity of begging in terms of behavioral cues such as calling frequency, stretching of the neck, and opening of the mouth in altricial birds. Generally, hungrier young tend to beg more intensely and a high calling frequency is needed to maintain a high feeding rate by parents. Thus, communication acts at two levels: within a brood, hungrier offspring might beg more intensively due to variation in hunger (short-term needs) among young, and in addition, begging intensity of the whole brood may vary according to the body condition (long-term needs) of young. Acoustic signals can be supported by visual signals of hunger as in canaries, where hungry young present more orange mouths to parents. As chicks grow up, the signal is intensified by the increasingly larger gape area of the brood. This signaling system is usurped by the cuckoo nestling, which, lacking a sufficient gape area, makes up for it by an extreme frequency of begging calls. Begging signals are not only used to obtain food but can also be presented when in need of other commodities. For example, young pelicans squawk when they get cool and thereby induce a parent to brood. As warmth is essential to the normal development of a young endotherm, begging for brooding is also a highly important aspect of parent–offspring communication in many precocial animals.

At present, we understand the complexities of the interaction between parental offering strategies and offspring begging behavior only to a limited degree. One interesting observation showing the close and subtle interdependence between the food provisioning rate of the parents and the begging intensity of chicks was made by Hussell (1988). In tree swallows, young tend to beg chronically more when the provisioning rate is low than when parents feed at higher rates, even at the same hunger state. This finding demonstrates that parent–offspring communication is finely tuned to the abilities of parents as well as to the state of offspring. Often, begging rates increase when parental care decreases: in tropical jays, the begging rate peaks 11 days later than the peak of parental provisioning and call rates in vervet monkeys increase between 8 and 10 weeks of age, associated with a decrease in maternal responsiveness.

Parents limit their investment in offspring and signal unwillingness to continue care when further demand of offspring would decrease their own future fitness gains. In such cases, parents may become outright aggressive against offspring and forcefully keep them away from continued lactation or food provisioning despite offspring signaling. In effect, they increase the cost of further care to the offspring to the point where it does not pay to insist. Thus, toward the end of parental care, a change in the state of parents ends the effectiveness of a previously smoothly functioning communication system even though individual recognition might persist for much longer.

Animal Communication: Signal Detection

R H Wiley, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Introduction

Signal detection theory (SDT) addresses the problem of identifying signals in noise. SDT derives from a fundamental feature of any mechanism for detecting signals, whether sensory, electronic, or otherwise – signals and noise cannot be differentiated with certainty. Signals (patterns of energy or matter with significance for the detector) are not distinct from noise (random or irrelevant energy or matter impinging on the detector from outside or arising in the detector itself).

Imagine a territorial bird in a forest singing its own songs and listening for its neighbors 50 to 200 m away. Some neural mechanism must distinguish between a neighbor's song at an appropriate distance and innumerable other possibilities – a neighbor's song close enough to indicate a territorial encroachment, a song of a newcomer looking for a place to settle, a song of another species with similar notes or frequencies, other sounds in the forest, and even random sounds produced by wind and turbulence. At a distance, any song arrives at the listener distorted by attenuation, reverberation, random amplitude fluctuations, and masking by sound of similar frequencies (Wiley and Richards, 1982). All signals are degraded during transmission, and all mix with background energy. In practice, absolute differentiation of signals from external noise cannot occur in real life. The degree to which signals and external noise are separable in actual (as opposed to theoretical) situations varies widely but is never complete. Furthermore, any mechanism for identifying signals generates its own internal noise and confusions.

Principles of Signal Detection

To analyze this situation quantitatively, SDT assumes that any such detectors can be represented by some combination of simple channels, each of which has two possible responses: go and no-go. The output from such a channel depends on the level of the input. It further assumes that noise is normally distributed energy in the same channel as the signal. In this case, the problem of signal detection is represented by the overlap of the probability density functions of the noise and the signal plus noise. The detector uses some threshold of input for a response: A level of input below the threshold results in no response (no-go); a level above the threshold results in a response (go) (**Figure 1**).

This formulation separates two aspects of signal detection. The inherent detectability of the signal is represented by the normalized distance between the peaks of the probability distributions for noise and signal plus noise. The bias of the detector is represented by the position of the threshold for response. By quantitatively separating the detectability of a signal from the subject's bias, SDT has made an important contribution to the study of sensory thresholds in psychophysics (Macmillan and Creelman, 1991; Macmillan, 2002).

Introduction

Signal detection theory (SDT) addresses the problem of identifying signals in noise. SDT derives from a fundamental feature of any mechanism for detecting signals, whether sensory, electronic, or otherwise – signals and noise cannot be differentiated with certainty. Signals (patterns of energy or matter with significance for the detector) are not distinct from noise (random or irrelevant energy or matter impinging on the detector from outside or arising in the detector itself).

Imagine a territorial bird in a forest singing its own songs and listening for its neighbors 50 to 200 m away. Some neural mechanism must distinguish between a neighbor's song at an appropriate distance and innumerable other possibilities – a neighbor's song close enough to indicate a territorial encroachment, a song of a newcomer looking for a place to settle, a song of another species with similar notes or frequencies, other sounds in the forest, and even random sounds produced by wind and turbulence. At a distance, any song arrives at the listener distorted by attenuation, reverberation, random amplitude fluctuations, and masking by sound of similar frequencies (Wiley and Richards, 1982). All signals are degraded during transmission, and all mix with background energy. In practice, absolute differentiation of signals from external noise cannot occur in real life. The degree to which signals and external noise are separable in actual (as opposed to theoretical) situations varies widely but is never complete. Furthermore, any mechanism for identifying signals generates its own internal noise and confusions.

Principles of Signal Detection

To analyze this situation quantitatively, SDT assumes that any such detectors can be represented by some combination of simple channels, each of which has two possible responses: go and no-go. The output from such a channel depends on the level of the input. It further assumes that noise is normally distributed energy in the same channel as the signal. In this case, the problem of signal detection is represented by the overlap of the probability density functions of the noise and the signal plus noise. The detector uses some threshold of input for a response: A level of input below the threshold results in no response (no-go); a level above the threshold results in a response (go) (**Figure 1**).

This formulation separates two aspects of signal detection. The inherent detectability of the signal is represented by the normalized distance between the peaks of the probability distributions for noise and signal plus noise. The bias of the detector is represented by the position of the threshold for response. By quantitatively separating the detectability of a signal from the subject's bias, SDT has made an important contribution to the study of sensory thresholds in psychophysics (Macmillan and Creelman, 1991; Macmillan, 2002).

Figure 1 Representation of the general problem addressed by Signal Detection Theory. Noise (random or irrelevant energy in a channel) produces a measurable level of activation of a detector. A signal is added to this noise to produce a higher level of activation. The detector responds or not, depending on whether or not the level of activation exceeds some threshold, which can be adjusted to higher or lower levels of activity.

Applications to Animal Communication

Signal detection creates some serious problems for animals in natural situations. Communication between widely separated individuals, as just described, often requires receivers to deal with heavily degraded signals. Communication in large groups of conspecific individuals requires receivers to identify signals (for instance, a mate's or offspring's call) in a background of other similar signals. This latter situation is traditionally called the Cocktail-Party Problem.

The attraction of female frogs to calls of potential mates in large choruses provides an example (*see* **Frog and Toad Communication**). A gravid female frog in a quiet environment usually approaches a loudspeaker playing a conspecific male's call. If the male's call is mixed with the sounds of a natural chorus of hundreds of males or with random noise in the same frequency band, the female approaches the speaker only if the signal/noise ratio (SNR) is sufficiently great. Apparently, below some SNR, the male's call is not differentiated from the background. If we now imagine a female in a natural chorus, listening to hundreds of males, we can calculate how many of those males' calls exceed the critical SNR for detection by the female. Because sound spreads approximately spherically from a frog, and thus attenuates approximately 6 dB for every doubling of distance from the source, only calls from nearby males exceed the critical SNR. The density of males in the chorus thus determines how many of them a female can hear distinctly from any one point. Two such studies have suggested that females can hear only two or three individual males in a chorus at a time (Gerhardt and Klump, 1988; Wollerman, 1999). The hundreds of others become indiscriminable noise. Although immersed in hundreds of potential mates, a female actually has only a few choices at any one moment. She must move around and thus take risks of predation to sample more than these few.

When presented with two loudspeakers and two males' calls, a female (at least in some species) usually approaches the one with the lower dominant frequency, an indication of its larger body mass. When these males' calls are mixed with background sound from a natural chorus, females do not make this discrimination so easily. Again there is a SNR below which the female no longer prefers the call with the lower dominant frequency. Apparently, her nervous system no longer distinguishes the difference. As predicted by SDT, this more complex task of discriminating between two signals of interest requires a higher SNR than the simpler task of detecting the presence or absence of a signal (Wollerman and Wiley, 2002). There are thus levels of SNR that allow detection of a signal but not discrimination among similar signals. A female frog in a chorus is even more constrained in choosing an optimal mate than she is in finding any mate.

Theoretical treatments of direct mate choice (discrimination) as a factor in sexual selection should consider these constraints on signal detection in real situations (Wiley and Poston, 1996).

Implications for the Evolution of Communication

Signal Detection Theory offers a way to address the effects of these constraints on the evolution of communication (Wiley, 1994, 2000). The inability of detectors, neural as well as others, to separate signals from noise in real situations leads to the inevitability of error in communication. Every time a detector samples its input and either responds or does not respond, there are four possible outcomes: a correct detection (when a signal is present and the detector responds), a false alarm (when the detector responds but no signal is present), a missed detection (when a signal is present but the detector does not respond), and a correct rejection (when no signal is present and no response occurs). The probabilities of each of these outcomes depends on both the inherent detectability of the signal and the bias (threshold) of the detector.

The idea of error in animal communication can cause confusion, but evolutionary adaptation provides a clear framework for thinking objectively about error. If a response to a signal is evolutionarily advantageous for a receiver in a particular situation (in other words, if it results in greater survival or reproduction of such receivers and ultimately in the

spread of alleles associated with this response), then false alarms and missed detections represent errors by the receiver.

The fundamental conclusion from Signal Detection Theory is that receivers must compromise between decreasing their chances of false alarms and missed detection. If a receiver raises the threshold for its detector in order to decrease the chance of false alarms, it thereby increases its chance of missed detections (Figure 1). These two probabilities cannot be simultaneously minimized.

By combining SDT with Decision Theory, we can calculate the optimal threshold for a receiver in a particular situation. Decision Theory calculates an expected utility for any decision (such as any level of threshold for response by a detector) as a linear combination of the payoffs for each outcome times their probabilities of occurrence. The probability of a correct detection when a detector samples its input equals the probability that a signal is actually present times the probability that the detector will respond when a signal is present. The probability of each of the other three outcomes is calculated in an analogous way. In the end, the expected utility for a particular threshold for response depends on the payoffs of all four possible outcomes, the frequency of encountering a signal (the probability that a signal is present at any moment), and the effect of the threshold on the probabilities of response when a signal is present and when one is not.

Theoretical treatments of the evolution of various features of communication have sometimes included the possibility of error by receivers. Often, error is included by making the probability of response to a signal less than 1.0. Sometimes, formulations include the payoffs of two alternative responses (or response and no response). Few, though, have included all of the complexity of the expected utility of a receiver's performance.

Adaptive Gullibility and Fastidiousness

One application of expected utilities to the behavior of receivers reached the conclusion that receivers could evolve either adaptive gullibility (allowing relatively more false alarms but fewer missed detections) or adaptive fastidiousness (allowing fewer false alarms but more missed detections), depending on the payoffs of the possible outcomes and the frequencies of signals (Wiley, 1994).

Responses to alarm calls might often evolve adaptive gullibility. Mate choice might often evolve adaptive fastidiousness. Adaptive gullibility is a situation in which receivers are inevitably vulnerable to deception. Adaptive fastidiousness is a situation in which receivers are usually unresponsive even to appropriate signals.

Signal detection also has consequences for the evolution of signalers. The expected utility of producing a signal depends on the probabilities and payoffs of responses by the intended receiver and by any unintended receivers (such as rivals, predators, or parasites). One consequence is that signalers must compromise between the advantages and disadvantages of more exaggerated (and thus more inherently detectable) signals as a result of responses by intended and unintended receivers.

Another consequence is that fastidious receivers (in the sense just described) favor signalers that produce inherently more detectable signals. Evolutionary exaggeration of signals to increase detectability can thus result from evolution of fastidiousness in receivers. Because mate choice often evolves toward fastidiousness, adaptations for signal detection can explain the exaggeration of signals for mate choice. In this way, signal detection theory provides an important complement to sexual selection as an explanation for the evolution of many signals in animal communication (Wiley and Poston, 1996).

Animal Communication: Vocal Learning

That we learn many of the sounds that we produce is clearly one of the most striking features of our own species. This learning is the basis of our rich language, which has no equal in any other animal, and it also leads to the differences in space and time that are a striking feature of language: languages, dialects, and accents differ across the globe, and they also change with time so that new words spring up while others fall from use. Curiously, although all of these phenomena have their animal equivalents, to find them, at least in the vocal domain, one must search beyond our closest relatives. Among the apes, gibbons (Hylobatidae) have the most striking vocal repertoires, with pairs singing wonderful duets that resound through the forest at dawn. The members of a pair learn to coordinate the sounds that they produce, but do not learn the sounds themselves: Hybrids even produce songs intermediate between those of their parent species. Efforts to 'teach chimpanzees to speak' met some success using sign language, but were an almost total failure when the animals were called on to use their voices. Although the vocal repertoires of chimpanzees in different localities do appear to differ, and dialects are most likely to arise through learning, this sort of evidence is equivocal: animals recorded under different conditions, as, for example, when disturbances or provisioning differs between sites, may use different parts of their repertoires or call more excitedly in one place than another. Thus, the samples may differ without vocal learning necessarily being involved. The best evidence to date of vocal learning in nonhuman primates is probably in marmosets, where the calls of animals placed in pairs or groups show subtle modifications to match those of their cage-mates.

When we talk of vocal learning, we are concerned with animals learning to modify the form of sounds they produce as a result of experience, and this is sometimes called production learning. We must distinguish between this and two other processes. Usage learning is learning to produce sounds in a particular context, perhaps novel or simply more limited, as, for example, when a young animal initially produces a call in many different situations but gradually comes to link it only to that situation in which it is appropriate. Comprehension learning is learning to understand the meaning of sounds, so that over time an animal comes to respond to them in an appropriate manner. As a result of these two processes, a dog may learn to bark when it wants a door to be opened and that the word 'food' is a good sign that it should go to the kitchen. But there is no evidence that dogs can modify the sounds they produce. They are not therefore 'vocal learners.' Animals that do alter the sounds they make as a result of experience may, as many do, make precise copies of sounds they hear, or they may achieve individual distinctiveness by avoiding matching the sounds of others, or they may innovate, generating a whole variety of sounds that are different from any they have heard or produced before.

In what species is there evidence of vocal learning in this sense? Among mammals, apart from ourselves, it occurs in three groups: seals (Pinnipedia), bats (Chiroptera), and whales and dolphins (Cetacea). In seals and bats, the evidence is not extensive, but nonetheless convincing. A harbor seal (*Phoca vitulina*) in the United States, reared by a couple in Maine and transferred when a few months old to Boston aquarium, could produce various phrases including his own name, Hoover, all apparently uttered in an impeccable local accent. In bats, it has been found that the young of greater horseshoe bats (*Rhinolophus ferrumequinum*) have echolocation calls that match in frequency those of their mothers. The calls of mothers become lower with age, but the calls that the young develop are those appropriate to the age of the mother, giving strong evidence that these are learned from her. In greater spear-nosed bats (*Phyllostomus hastatus*), calls are group specific and

That we learn many of the sounds that we produce is clearly one of the most striking features of our own species. This learning is the basis of our rich language, which has no equal in any other animal, and it also leads to the differences in space and time that are a striking feature of language: languages, dialects, and accents differ across the globe, and they also change with time so that new words spring up while others fall from use. Curiously, although all of these phenomena have their animal equivalents, to find them, at least in the vocal domain, one must search beyond our closest relatives. Among the apes, gibbons (Hylobatidae) have the most striking vocal repertoires, with pairs singing wonderful duets that resound through the forest at dawn. The members of a pair learn to coordinate the sounds that they produce, but do not learn the sounds themselves: Hybrids even produce songs intermediate between those of their parent species. Efforts to 'teach chimpanzees to speak' met some success using sign language, but were an almost total failure when the animals were called on to use their voices. Although the vocal repertoires of chimpanzees in different localities do appear to differ, and dialects are most likely to arise through learning, this sort of evidence is equivocal: animals recorded under different conditions, as, for example, when disturbances or provisioning differs between sites, may use different parts of their repertoires or call more excitedly in one place than another. Thus, the samples may differ without vocal learning necessarily being involved. The best evidence to date of vocal learning in nonhuman primates is probably in marmosets, where the calls of animals placed in pairs or groups show subtle modifications to match those of their cage-mates.

When we talk of vocal learning, we are concerned with animals learning to modify the form of sounds they produce as a result of experience, and this is sometimes called production learning. We must distinguish between this and two other processes. Usage learning is learning to produce sounds in a particular context, perhaps novel or simply more limited, as, for example, when a young animal initially produces a call in many different situations but gradually comes to link it only to that situation in which it is appropriate. Comprehension learning is learning to understand the meaning of sounds, so that over time an animal comes to respond to them in an appropriate manner. As a result of these two processes, a dog may learn to bark when it wants a door to be opened and that the word 'food' is a good sign that it should go to the kitchen. But there is no evidence that dogs can modify the sounds they produce. They are not therefore 'vocal learners.' Animals that do alter the sounds they make as a result of experience may, as many do, make precise copies of sounds they hear, or they may achieve individual distinctiveness by avoiding matching the sounds of others, or they may innovate, generating a whole variety of sounds that are different from any they have heard or produced before.

In what species is there evidence of vocal learning in this sense? Among mammals, apart from ourselves, it occurs in three groups: seals (Pinnipedia), bats (Chiroptera), and whales and dolphins (Cetacea). In seals and bats, the evidence is not extensive, but nonetheless convincing. A harbor seal (*Phoca vitulina*) in the United States, reared by a couple in Maine and transferred when a few months old to Boston aquarium, could produce various phrases including his own name, Hoover, all apparently uttered in an impeccable local accent. In bats, it has been found that the young of greater horseshoe bats (*Rhinolophus ferrumequinum*) have echolocation calls that match in frequency those of their mothers. The calls of mothers become lower with age, but the calls that the young develop are those appropriate to the age of the mother, giving strong evidence that these are learned from her. In greater spear-nosed bats (*Phyllostomus hastatus*), calls are group specific and

change when membership of the group changes. The evidence in whales and dolphins is more extensive. Bottlenose dolphins (*Tursiops truncatus*) have been trained in captivity to mimic computer-generated sounds. In the wild, young animals develop a call (referred to as a signature whistle) that is more or less peculiar to themselves. Those of young males, which leave their natal group, are often similar to their mothers' calls, whereas those of young females tend to diverge. As females stay together, this suggests that they are modifying their calls to be different from others in their group, whereas males need not do so as the group they move to is different. In humpback whales (*Megaptera novaeangliae*), the evidence concerns lengthy songs rather than whistles. These animals produce songs that consist of a long series of elements lasting many minutes. All of those in an area sing identical songs at any one time, but the songs slowly shift during the season and between years. The songs of two animals in a particular year are more similar than the songs of one animal in two successive years. Given that these are very long-lived animals, such rapid shifts in song matched between individuals could be achieved only by learning.

Some of the best examples of vocal learning come from birds. Parrots (Psittaciformes) are an obvious example, with the well-known capacity of those kept as pets to imitate human speech and many of the other sounds in their everyday environment. Though they have not been extensively studied in the wild, this ability seems to emerge from their need to imitate the calls of others of their own species. It has been used in laboratory studies to explore their cognitive capacities: unlike chimpanzees, they can learn to produce many words, and will, for example, use them in the right context and recombine them in appropriate ways.

Two other groups of birds show vocal learning, the hummingbirds (Trochilidae) and the songbirds (Oscine passerines). Hummingbirds sing and there is evidence that they learn their songs, though they have been studied relatively little. On the other hand, an enormous amount of work has been devoted to the study of vocal learning in songbirds. These comprise approximately half (~4000) of all bird species. Many of them have elaborate songs and are easily kept and bred in captivity, so that their vocal development can be studied experimentally in great detail. In every case where such a study has been carried out, and this has now involved some hundreds of species, learning has been found to play a part in the development of their song. In most cases, this learning involves the accurate copying of the songs of others, but in some cases, songs are also generated *de novo* without copying from others. Songs are often long and complicated and this may be one reason that they are learned, but generating complexity cannot be the only answer as learning often also plays a part in the development of simple call notes such as those that birds use to keep in contact with one another.

Because birdsong has been so extensively studied, it is worth going into some detail on how it develops: This is well illustrated by the case history of the chaffinch (*Fringilla coelebs*) outlined in **Figure 1**. In the tropics, females often sing and may join their mates in remarkable coordinated duets. But, at least in temperate parts of the world, elaborate songs are almost entirely a male prerogative and tend to be restricted to the breeding season as their main functions are to attract mates and to repel rivals. Field observations show that neighbors often have closely similar songs, whereas those of males some distance apart may be very different, sometimes forming clear dialects. A good example here is the white-crowned sparrow (*Zonotrichia leucophrys*) in California, in which each male has a single short and simple song that is shared over quite an extensive area. Such observations suggested that songs might be learned, but experiments were required to show that they were. The clinching evidence comes from hand-rearing experiments. Young birds taken from the nest at a few days old develop very rudimentary songs if kept in isolation so that they could not hear any adults; on the other hand, if the young were played the taped songs of adults, they copied them very precisely. A more extreme form of deprivation is deafening: in this case, the young birds were not only unable to hear adults but could not hear their own efforts either, and the outcome was little more than a screech.

Birds do not generally learn the songs of species other than their own and this suggests that they hatch with a predisposition to copy sounds of one sort rather than another. Young white-crowned sparrow chicks memorize sounds well before they sing themselves and, at this early stage, they respond by chirping more to their own species' song than to songs of other species. Social interaction may, at least to some extent, override such channeling of preferences, so that young birds reared by, or in close contact with, another species may learn its song rather than their own species song. But this varies a great deal. In cases where song is rather stereotyped, it is most likely if the song of the foster species is like that of the bird's own, as, for example, when a zebra finch (*Taeniopygia guttata*) will copy the song of a Bengalese finch (*Lonchura striata*). On the other hand, there are cases where not even interaction is required for young birds to learn a great variety of sounds from many other species around them, as in mockingbirds and starlings. Some, such as thrushes that imitate

Figure 1 Chaffinch song development: a case history. Chaffinches provide a good example of how nature and nurture interact during the course of song development in songbirds. (A) An example of a typical adult male song. All chaffinch songs have this general structure, consisting of a series of phrases within which the same element is repeated a number of times, followed by a 'flourish' of unrepeated elements. If a young bird is hand-reared without any opportunity to hear adult song, the song he develops is much simpler (B). It is approximately the same length and frequency as normal and also consists of a series of elements, but these do not fall into clear phrases, tending instead to drift in structure from one to the next. The flourish is often short or absent. This pattern acts as a constraint on what chaffinches will learn, and they seldom copy from other species. However, if a young male hears the song of an adult, he will often copy it with great fidelity, provided that he experiences it in the first few months of his life, before he comes into full song himself, which he does in the spring after he hatches. (C) The top song was played to a young male when he was a fledgling, and the bottom song is the copy of it that he produced the following spring, several months later. The number of elements in a phrase differs, as it does from one song to the next within a bird, but the copy is exact. Birds will also copy in the following spring as they start to sing themselves and will build up a repertoire of up to five song types. (D) Examples of two tape-recorded songs played to a young male in this first spring (top trace of each pair) and beneath them the copies that he produced. The songs in the first pair are near identical, but there are differences between the bottom songs. For example, the flourish on the tutor tape is longer and rises and falls, whereas that of the young bird is short and lacks the down-sweep at the end. That copying is not always totally accurate leads to a song changing over time and also varying in space, and in some species this can lead to quite distinct dialects.

telephones and lyrebirds that copy chainsaws, do not even draw the line at birds' sounds.

Whatever they copy, birds often memorize it well before they start to sing themselves, as shown for the chaffinch in Figure 1. The process of memorization is frequently restricted to a 'sensitive phase,' most often when the bird is a fledgling or young adult, and once in full song it is unusual for any change to take place. Young adults sing highly varied 'subsong' when they first start to sing and this later crystallizes into full song, which is much more stereotyped. There is evidence in several species that they memorize many songs, and produce these in subsong, but that only some survive into the adult repertoire. Those that persist are often songs that match those of neighbors, with which they can therefore countersing across their territory boundaries. This phenomenon, of memorizing more than they subsequently sing, is referred to as 'action-based learning.' Whereas the original songs are memorized in the same way as in normal production learning, their subsequent selection is a matter of usage learning, as defined above. At an even greater extreme is song learning in brown-headed cowbirds (*Molothrus ater*). These are brood parasites, so that the chicks have no opportunity to hear adult song. But they form flocks after fledging and the males develop their songs at this stage. They then produce many different sounds and the females they are with show a display to those phrases that attract them; this then stimulates the males to repeat these particular sounds. They thus end up with songs that are well matched to the preferences of females in their group. The females themselves do not sing, but their displays appear to condition the males to develop songs that they prefer.

We know a great deal about the mechanism of vocal learning, particularly in songbirds, but one question to which there is as yet no clear answer is: Why do they learn? Many learned sounds are simple calls, and some quite complex songs, like those of gibbons and of suboscine birds, are not learned. Thus, the answer does not simply lie in the generation of complexity. It may nevertheless be the case that song learning is essential for the generation of the large song repertoires that are found in the males of some species. There is evidence that females prefer these large repertoires and one reason this may be the case is that only well-nourished and healthy males that have withstood the stresses of development can generate the brain mechanisms necessary to achieve such large repertoires. Beyond this, there is evidence in some species that learning may help to match the sound to the habitat, and in others that males may learn from their fathers and that females may avoid inbreeding by choosing mates that sing differently. Learning may also lead to individuality and so assist in processes of vocal recognition. But these and other ideas that have been put forward cannot account for more than a few cases. The fact that song learning is widespread among songbirds yet almost totally absent among their closest relatives suggests that it evolved near the origin of that group and has been retained by them all. It is possible that it does not even have a function in itself, but that any male that was to lose the ability and any female that preferred a male with such a more restricted unlearned song might be at a disadvantage because they had a more limited choice of mates. In other words, learning of song may persist because those that show it are caught in a 'cultural trap.'

Annadurai Conjeevaram (1909–1969)

F Britto, Sophia University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Annadurai, popularly known as *Ariñar Anna* 'intellectual elder brother,' was born on September 15, 1909, as the son of Natarajan, a poor weaver in Conjeevaram. He died on February 3, 1969 in Chennai, as the chief minister of Tamil Nadu. He completed his university studies (1934) at Pachaiyappa's College, Chennai, majoring in economics and politics. As a disciple and lieutenant of E. V. Ramaswamy, an atheistic social reformer, he matured into a radical opponent of Brahmin supremacy, religious superstitions, and Hindi imposition. In 1949, he founded his own political party, DMK (Federation for the Progress of Dravidians). He served as a member of the Indian Parliament (Rajya Sabha) from 1962 to 1966, opposing the imposition of Hindi and advocating the cause of the Tamils. In 1967, he led DMK to a landslide victory over the mighty Congress party and became the chief minister of Madras state. During the two years that followed, he initiated reforms that have substantially affected the linguistic map of India and Tamil Nadu.

Annadurai was not an active linguist, but a linguistic activist, who held Tamil language, literature, and culture in high esteem and strove to create an environment where Tamil could flourish without succumbing to Hindi (Sivaswamy, 1968; Ramachandran, 1985; Ganesan, 2003). Although he was a prodigious writer of letters, essays, stories, novels, plays, and movies (see Santaanam, 1992), he rarely wrote on language or linguistics as such. He contributed to the Indian language debate mainly by eloquent speeches (see Moorthy, 1975a, 1975b; Ramachandran, 1975), administrative ordinances, and political activism, having been jailed several times for his protests against the imposition of Hindi.

Annadurai's lasting language-related contributions are: (1) He had the name of the state changed from Madras to Tamil Nadu in 1968, so that the state was identified by the language spoken in the region, instilling pride among the Tamils and stimulating planned and unplanned development of the language; (2) In a similar vein, he introduced numerous Tamil equivalents for all state-related offices and enterprises, such as *Tamilaka Aracu Talaimai Ceyalakam* 'Chief Secretariat of Tamil Nadu Government,' creating a remarkable growth in the vocabulary of Tamil; (3) He efficiently blocked Hindi from becoming the sole official language of India and indirectly helped English survive in India, by introducing a two-language formula (Tamil and English) in Tamil Nadu. He argued his case by pointing out that Tamils would face the burden of having to learn two foreign languages compared to the one or none learned by Hindi natives, and that Tamils would be at a great disadvantage nationally, unable to communicate in Hindi like the natives; (4) He fueled the growth of Tamil by encouraging Tamil scholars to modernize the language and establish centers of Tamil learning; (5) He stirred up a passion for Tamil by his own highly appreciated oral and written discourses, leading a large number of youths to imitate his oratorical and rhetorical styles and to study the language and culture; (6) Since 1967, Tamil Nadu has been governed by different offshoots of DMK, and each has contributed to the growth of Tamil in varying degrees, driven by the linguistic policies Annadurai had set.

Annadurai, as the chief minister, hosted the Second International Tamil Conference in January 1968 in Chennai, and he visited Yale University in May 1968 as the first non-American recipient of the Chubb fellowship. He was awarded an honorary doctorate by Annamalai University in September 1968. The Indian government issued a stamp in his honor in 1970 and published a formal biography in the series *Builders of modern India* (Ganesan, 2003). Tamil Nadu has erected thousands of statues and named many bridges, squares, and streets in his honor.

Antarctica: Language Situation

Mostly uninhabitable, Antarctica has a terrain of which 98% is a thick continental ice sheet and 2% is barren rock. It is the fifth largest continent, which with its 14 million sq km surpasses in size both Australia and the European subcontinent. Notwithstanding its considerable mass, Antarctica was long believed to be made up of a group of islands, an idea that was dispelled only in 1840. After World War II, scientists took an increasing interest in Antarctica and year-round research stations started appearing on the continent. A much needed legal framework was set up in the late 1950s in order to regulate the activities of the different nations carrying out research in Antarctica. The Antarctic Treaty, which entered into force in 1961, continues to govern the actions of the people in Antarctica. Even though Argentina, Australia, Chile, France, New Zealand, Norway, and the United Kingdom have made, at times overlapping, territorial claims – neither recognized nor denied by the Treaty – no single nation controls Antarctica. The continent is in fact administered through meetings of the 27 Antarctic Treaty consultative member nations, which together with the 18 nonconsultative nations constitute the 45 Treaty members (in 2003). Although the latter represent about two-thirds of the world's entire population, the number of persons present in Antarctica varies from approximately 4000 in summer to 1000 in winter, with an additional 1000 carrying out research in the waters of the Treaty region. It is not unusual for Treaty nations to be represented by a single person in Antarctica; all the individuals on the continent come under the jurisdiction of their own countries, although certain laws of the United States, such as the Antarctic Conservation Act, have a direct application in Antarctica. The Treaty itself has been drafted in English, French, Russian, and Spanish, each version being equally authentic; similarly, the meetings are held in the four languages of the treaty system.

Anthropological Linguistics: Overview

H E Manelis Klein, State University of New York, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Anthropological linguistics is a subdiscipline within the discipline of anthropology. It grew out of the anthropological concern for unwritten exotic languages and was and remains firmly grounded in both field linguistics and linguistic methodology. The intellectual basis for anthropological linguistics in the United States derives from Boas (1911), whose interests and concerns led to the anthropological view of language, which is that language is an integral part of culture and, therefore, to be a good anthropologist one needs to understand and/or speak the language of the culture one is studying. It is this view of language that is most relevant to the definition of anthropological linguistics. In other words, one approaches language from an anthropological view, which includes the uses of language and the uses of silence, as well as the cultural problems involved in silence and speech. Anthropological linguistics is Boas's concept of getting language to work with culture.

History of Anthropological Linguistics

Anthropological linguistics is not attributable only to Boas, but rather we have to go back further in time to a variety of influences. In the United States, Boas was mentored by John Wesley Powell and encouraged to work on the indigenous languages of North America. Powell's agenda was to be able to work out the genetic relations of these indigenous languages, so that their classification could be accomplished – a task which the Bureau of American Ethnology wanted to see done because of their interest in equating language

Introduction

Anthropological linguistics is a subdiscipline within the discipline of anthropology. It grew out of the anthropological concern for unwritten exotic languages and was and remains firmly grounded in both field linguistics and linguistic methodology. The intellectual basis for anthropological linguistics in the United States derives from Boas (1911), whose interests and concerns led to the anthropological view of language, which is that language is an integral part of culture and, therefore, to be a good anthropologist one needs to understand and/or speak the language of the culture one is studying. It is this view of language that is most relevant to the definition of anthropological linguistics. In other words, one approaches language from an anthropological view, which includes the uses of language and the uses of silence, as well as the cultural problems involved in silence and speech. Anthropological linguistics is Boas's concept of getting language to work with culture.

History of Anthropological Linguistics

Anthropological linguistics is not attributable only to Boas, but rather we have to go back further in time to a variety of influences. In the United States, Boas was mentored by John Wesley Powell and encouraged to work on the indigenous languages of North America. Powell's agenda was to be able to work out the genetic relations of these indigenous languages, so that their classification could be accomplished – a task which the Bureau of American Ethnology wanted to see done because of their interest in equating language

with culture. Boas felt that a practical reason for linguistic studies was for ethnological purposes; that is, language provided a better understanding of cultural phenomena which on the surface appear to have no connection with language, but which without language cannot be understood. He noted that there were unconscious concepts in the mind which remained covert, never surfaced, but were clearly related to the culture, e.g., religion and table manners. However, it is important to note that Boas essentially refuted Powell. He did not think of language or culture in evolutionary terms, as Powell did, but rather he introduced the concept of cultural relativity. Both cultural and linguistic relativity are expressed in the statement that all languages are equal but not the same, that is, one language is as good as another. Furthermore, the earlier concerns of Humboldt had an important impact on the European interest in the field and certainly Boas and his followers were aware of their predecessors' interest in exotic languages.

Boas believed that there was no correlation between language and culture and also none between language and race. He focused on what is known as 'salvage anthropology,' that is, documenting languages spoken by fewer and fewer people so as to have a record of those languages before they disappeared. His approach to documenting these languages was more rigorous than earlier efforts and he trained a number of scholars to follow his intellectual lead. Languages were important to study because they encouraged field workers to be closer to the data they were collecting as well as because they provided insight into the culture through the linguist's ability to get at the "categories and rules of language" (cf. Duranti, 2003).

The philosophical underpinnings of anthropological linguistics became more complicated after Boas. Voegelin (1965: 484–485) noted that "research concerned with eliciting relevantly in linguistics is the concern of anthropological linguistics." The rest of Voegelin's program, however, was not the same as that of Boas's followers. Actually, in the United States two schools appeared, both with anthropological linguistics as the name for the discipline: Boas, Sapir, and Whorf on the one hand and Bloomfield, Kroeber, and Voegelin on the other. From these two schools anthropological linguistics emerged as a serious part of humanistic inquiry. Anthropology became the discipline within which to study linguistics. Students in the formative part of the discipline were students of either Leonard Bloomfield or Edward Sapir. Their orientation was towards field linguistics and not towards historical linguistics, which had been the prior focus of the field. This was the result of their view that language represented culture, both present and past.

Bloomfield, who became known as the father of American descriptive linguistics, focused primarily on linguistic form, pushing function and meaning to the periphery. Sapir, on the other hand, noted that although cultural behavior was patterned in both form and function, it was largely unconscious patterning. Elaborating on this position, Sapir (1927) remarked upon the lack of awareness of speakers about their language behavior and tied it to gestures, which are also culturally covert, and even to human economic behavior.

For several generations after Boas's period of fieldwork and training students, the Boasian view of linguistics as the mechanism by which anthropological fieldwork could be better accomplished was the primary motivation for the field of anthropological linguistics. In other words, anthropological linguistics was defined as a construct of anthropologists to explain the relationship of language and culture. As time went on, however, other theoreticians, linguists, and anthropologists came to focus on identifying the discipline differently and began to challenge the earlier foci.

Main Currents of Anthropological Linguistics

In order to understand the evolution of anthropological linguistics, one also needs to understand the works of Sapir, a student of Boas, who is thought to have provided the line of thinking about language that led ultimately to Noam Chomsky's works. Chomsky's influence on linguistics has perhaps been, as some have said (Duranti, 2003), the diminution of interest in anthropological linguistics.

In 1957, with the publication of Noam Chomsky's *Syntactic structures*, the focus on language was different. Prior to this pivotal point, the major linguistics approach in the United States was identified as American descriptivism or structuralism. It was the methodology that arose primarily from the need to describe languages that had not been previously analyzed. But, due to the Chomskyan approach, which signaled that description or classification of the various linguistic systems was not sufficient, and which was rule based, people began to focus on the rules by which a speaker of a language produces sentences and therefore understands them. The interest in language then turned from language description to the the rules that produce sentences, which were thought to reflect natural mental processes. It was thought that understanding the nature of the rules would help explain the inner workings of the human mind.

The early period of anthropological linguistics, the natural outgrowth of Boas's four-field approach to

anthropology (cultural anthropology, physical anthropology, archaeology, and linguistics), was especially important for the way in which anthropologists tried to interpret one culture to another. In order to accomplish this, it was important to learn the language and not use an interpreter. Thus, field linguistics was a natural outgrowth of that approach. The focus was on understanding, not just producing language. Techniques were developed for learning to understand exotic languages and a focus on conscious awareness of language learning was evident. Of course, there have been some anthropological linguists who have indicated that the best way to learn the target language was just to listen, to learn about the society, and then to try to speak (Burling, 1970). But, on the whole, as a result of Boasian efforts, the field linguistics approach has predominated.

Tasks of Anthropological Linguists

Anthropological linguists study human languages. As noted earlier, this focus developed because of the immediate need to describe large numbers of unwritten languages. However, in addition to language description and as a direct result of involvement in languages with structures so different from the Indo-European languages known to investigators, several other lines of inquiry emerged. One of these areas of interest was the relevance of language to the study of human behavior and incidentally to the various fields of anthropology. In the process of following this stream of interest, several themes became prominent. One is the focus on linguistic meaning and how it affects behavior. Related to that focus is a recurring discussion of what is known as the Sapir–Whorf hypothesis. In its strongest version it is stated that language, especially grammatical structure, directs perceptions; however, it is generally agreed that that is not so. This hypothesis attributes language, especially grammatical structures, to be the determiner of human perception.

Furthermore, it is important to clarify that Whorf never used the term 'hypothesis' for his attempts at understanding the relationship between language and thought. Nor did he espouse any form of linguistic determinism. In fact, Whorf's work has been seriously distorted by linguists and philosophers. Rather, he was focusing on what has been called linguistic relativity. But even this term does not express what Whorf was really trying to say about language and thought and culture. Whorf was trying to discuss the interconnectedness of language and thought and culture and wanted to understand that each of these aspects were interconnected – but they did not determine each other.

Nevertheless, a few scholars went along with Whorf's hypothesis at its most abstract. Harry Hoijer felt that the only way to understand the Navajo mind was through understanding and learning the Navajo language. He claimed that there was a correlation between the world view implied by the Navaho verb system and the passivity and general restlessness or fatefulness of Navajo mythology. This position is not widely accepted.

The issue still remains as to how to get at the thoughts of the speakers of a language. Thus, anthropological linguists maintain their interest in the connections between language and the rest of culture.

Related to the issues of language, thought, and behavior are important factors in dealing with the differences between different cultures speaking the same language and different languages spoken by essentially the same culture. Also, the putative relationship between language and physical type has been shown to be nonexistent (for example, the Athabaskan family of languages, which is spoken by people of different physical types, and the obverse, that is, one physical type speaking many different languages, as is the situation in New Guinea).

Related to the basic issues that have grown out of an attempt to understand the relationship between language and perception is the discussion of the character of linguistic categories, namely that they are an unconscious part of language use. Thinking along these lines has led to an attempt to figure out the methodology for determining how people think about their world of experience from the way in which they talk about it. This in turn has led to classification efforts and terminological systems. Taxonomies, segregate sets, discovery procedures, and attributes were part and parcel of the focus on the unconscious use of linguistic categories.

Much of the discussion about the relation between language and thought, as a result of the statement, restatement, and analysis of the tradition of the Whorfian view in the United States, was due to the strangeness of the languages that the linguists were studying in the Americas. There was a clear relation between exoticism and the focus on language and thought. The interest in exoticism together with Boas's determination to seriously study the native languages of the United States led to the focus on field linguistics and the importance of good linguistic elicitation techniques. Unlike first-language acquisition, which is primarily unconscious, learning a second language, especially in a field situation, is a different matter. In other words, the description of a foreign language is part of ethnographic fieldwork. The anthropological linguist is concerned primarily with this aspect of ethnography, but any anthropologist

studying a foreign culture must know the techniques of learning a language with which he or she is totally unfamiliar.

There are certain basic assumptions of the anthropological linguist in the field. One starts by assuming knowledge of nothing. Fieldworkers usually are academics trained in the general procedures of the discipline and know about language structure in general. They have a general knowledge of the technical processes by means of which they can learn a particular language, but compared to other disciplines which operate under a set of assumptions, anthropologists start with a blank slate. Optimally, fieldworkers have no specific theory that they want to test, but rather are aware that they are human and have certain predispositions from their own culture which can and must be overcome by working with someone from the 'other' culture. Furthermore, by using a consistent methodology, anthropological linguists have tried to lead the way for cultural anthropologists also to achieve both consistent and valid results in their research, which is a very hard undertaking. Nevertheless, social science disciplines recognize the contribution that anthropological linguistics has made especially to field linguistics. The most common example of this is provided by Lévi-Strauss, who noted that the discovery procedures utilized by anthropological linguistics allowed researchers to arrive at conscious or surface manifestations of cultural items from unconscious or underlying or deep structures. The concept then of underlying or unconscious structures for cultural anthropologists was an approach taken directly from linguistics, which in its analysis of language noted that all language is basically unconscious and automatic behavior, that one can't talk about one's automatic behavior, but that one can, through deductive methodology, generalize about automatic behavior from observable or surface behavior. Thus, cultural anthropologists borrowing these concepts perceived that the unconscious behavior as noted in phonemics and the conscious behavior that results in phonetic systems could be generalized to discuss cultural behavior, that is, the 'etic' or surface behavior which Lévi-Strauss called 'cooked' and the 'emic' or underlying behavior which he called 'raw.' This methodology is useful for the cultural anthropologist because it signifies that meaning can be deduced from overt responses by checking one's first possible perceptions in different environments. The conclusion by scholars then was that cultural differences can be studied essentially the same way that linguistic differences are studied.

As noted earlier, one of the distinguishing features of anthropological linguistics is its importance to the field of cultural anthropology. Nowhere is this more obvious than in the way in which ethnographic studies rely on linguistic methodology. The cultural anthropologist relies on language in order to be able to translate the significant categories of the culture. Frake (1972) commented that we understand culture because of the way that people speak about their experiences. In other words, a culture is like a grammar in that it has a set of rules that enables members of the culture to interact with each other and understand and be understood. Thus, an ethnography can provide the guidelines for behavior in the same way that a linguistic grammar provides the guidelines for proper language behavior.

The relationship of linguistic structure and theory to cultural systems is that which is emphasized in anthropological linguistics. This is done by utilizing the basic knowledge of linguistic systems and by then relating the linguistic forms to their analogues in cultural systems. By utilizing field method techniques, one gains ability in interviewing and in interpreting verbal communication to gain both linguistic and cultural information.

During the period when anthropological linguistics was the most significant approach to studying unwritten languages, the question would arise about the methodological correctness of the investigator. How to ensure that every analysis could be replicated became one of **the** issues of anthropological linguistics and one that ultimately led to the further division of anthropological linguistics during the transformational revolution attributed to Noam Chomsky. The effort to avoid contradictory results, especially in phonetics and phonology, was a challenge that led to analyses all of which, even if different, were convertible. And, just as cultural anthropologists begin their training by learning something about the diversity of human customs, anthropological linguists have to learn about the incredible variety of sounds and their meaning in the languages of the world.

Part of one's knowledge of one's native language includes knowing what sound sequences occur in the language. But how does someone who studies less well-known languages figure that out? The early part of fieldwork requires concentrating on the sounds that native speakers of the field language utilize. This aspect of study is called phonetics, which is the scientific study of speech sounds and includes the study of the physiology of speech production and the physical signals that emerge from the speaker (studied with the aid of computers and other machines), as well as the mechanisms of speech perception. Articulatory phonetics, one branch of phonetics, deals with the ways in which sounds are classified and is the area of phonetics that is of most interest to anthropological linguists. It is a tool which is most useful to them

because they often work with unwritten languages and need a way to write down what their language consultants are saying. Articulatory phonetics provides the means.

After listening and recording some segments of natural speech in the field language, the trained field linguist begins to analyze the symbols which are used to find out the inventory of vowels and consonants. The sounds that these symbols represent do not occur in the abstract. In fact, they usually occur only in particular positions within words. So, the process involves figuring out what kinds of word structures or canonical forms occur in the language. From that one works on ascertaining larger units and figuring out the meaning of stress and nasalization, checking to see if either is significant. One component of phonetic analysis involves determining what are the phonetic features of the particular language. This involves analyzing the airstream mechanism, voicing, nasal vs. oral sounds, articulatory modifications of the sounds, and the manners of articulation, as well as the specific features of the vowels. Some languages are pitch languages, which, for the speaker of English, are harder to analyze, while other languages are intonation languages, like English, and therefore easier for English speakers to process. Once the anthropological linguist has gathered the raw phonetic data, another technique is used to process that data in order to decide what are the important units of sound (phonemes), and then to symbolize them so that the native speaker of the language can learn to read them. A clear advantage to doing this is that once one can identify the significant sounds of a language, one can easily identify whether the series of sounds can be a possible utterance in the language one is studying. So, given a sequence of sounds, a speaker/hearer can accept or reject it as a possible utterance because of what she or he knows about the structure of that language. One's phonological knowledge allows one to distinguish possible from impossible words. It is also productive, because it helps the speaker or analyst to create new words.

Linguists have known for a long time that every person is a native speaker of at least one language and that by the time children reach the age of five or six, those children are proficient speakers of their native language. On the other hand, when a child or an adult learns a second language, they usually encounter some kind of problem, often with the phonology of the new language. Anthropological linguists often deal with the issues that surround speakers' imperfect abilities in the new language and mediate the social stereotypes that arise from these problems.

Another aspect of anthropological linguistics that is clearly a part of the study of unwritten or less known languages is the issue of what is the meaning of the string of sounds one hears. In analyzing languages, the linguist is interested in both the smallest units of meaning as well as the larger meaning units. The minimal unit of meaning is called a morpheme and the study of these units is called morphology or the morphemic structure of words. Morphemes can be independent words, also called free morphemes, or they can be parts of a word, also called bound morphemes.

Syntax or the way in which words are combined to form grammatical phrases and sentences is another aspect of language study. Syntactic knowledge enables a speaker to distinguish, for example, between a noun and a verb, between a future tense and a past tense, or between a genitive and an ablative case.

Still another aspect of study for the anthropological linguist is semantics, which broadly means the study of linguistic meaning. Another way of stating this is that semantics consists of the rules which tell a speaker how to choose the right meaning of a word to correlate or connect with the other words in a sentence. It helps the speaker decide which words can cooccur in a sentence; that is, it enables one to choose the right meaning of a word to cooccur with other words. The relation between sound and meaning is complicated. Once anthropological linguists have done some analysis of a language, they are able to understand different sentences which show new combinations of the categories they have arrived at. In other words, sentences can be formed and recombined, following a limited number of rules. This allows for the flexibility which is the hallmark of human creativity and indicates one of the ways that human speech is different from the means of communication of any other species.

Finally, narratives or discourse or pragmatics are also in the purview of anthropological linguistics. Field linguists know they have done their research well when they are able to analyze a body of textual material.

Wider Concerns of Anthropological Linguistics

When we begin to study a language, using an anthropological linguistic approach, we focus on what phenomena are important to the speakers of the language and also how they organize those phenomena into coherent rules. These rules, semantic in nature, can only be discovered by undertaking a systematic study of the system of meanings that each language deems important. Analyzing a language is the easiest and fastest way to discover the system of meanings of a culture. The linguistic tool most used to do this is

classification or categorization. Classification is a way in which humans can deal with the complexity of their environment by identifying things and happenings quickly and thereby making their lives more efficient.

The relevance of linguistic methods to ethnographic studies, especially in terms of eliciting meaning, is that anthropological linguists want to discover the native categories, the classification system, of their informants, thereby gaining an understanding of the items and events that are important to that culture. The notion of classification as being important is first clearly noted when one is trying to learn the sound system of a language and so anthropological linguists must first discover the native categories of sound through phonological analysis. Anthropological linguists must also study semantic categories because they must know how to speak the language. Once they have a speaking knowledge of the language, they must discover the higher-order categories the language encodes. This can be done by looking for the names of things and how the culture organizes these names into larger groupings. In fact, the names that a culture gives things are an indication of the importance that those things have to the culture. This type of research or analysis is called ethnographic semantics. Although it was an important part of the tool kit of anthropological linguists in the middle of the 20th century, now it is more often the purview of cognitive linguists. Ethnographic semantics, which has also been called ethnoscience or the 'new' ethnography, used the models of grammatical analysis. It was concerned with discovering native categories and also with stating the rules for generating these categories. Underlying this method was the fact that anthropological linguists could not necessarily expect the native categories that were revealed to correspond to their own native categories. The discovery and use of semantic categories is considerably more difficult than discovering phonological and morphological categories.

Although ethnographic semantics was one of the approaches that anthropological linguistics used to get a better understanding of the meaning systems of a language, there were and are other approaches of interest to the investigations of language that anthropological linguists like to use, such as that of searching for semantic universals.

Once anthropological linguists have established what they believe to be the language norms and gained some understanding of the overall cultural norms of the people who speak the language under study, a finer-grained type of analysis often emerges. Questions then arise as to how people differ in their language behavior. This can be studied both synchronically and diachronically, as we note that language change is slower than cultural change and largely unconscious. Because cultural change is faster we note that in languages, the most cultural part is the vocabulary and so vocabulary or lexemes change faster than other parts of the grammar.

Yet another related area of interest to anthropological linguists is that of dialect differentiation. Different subgroups within a culture have different systems of speaking. Two dialects are two different ways of speaking which are basically similar in their whole grammatical system, but which only slightly differ from each other. The differences are not simple ones such as a difference of pronunciation, but rather include a cluster of features which follow a predictable pattern. Regional dialects often evolve which show that one differs from another by a set of phonological, grammatical, lexical, and/or semantic features. Many cultures also have different dialects that are utilitarian, used for ritual purposes compared to nonritual language. Furthermore, dialect differentiation also evolves as a result of the development of different social classes education, occupations, and generations.

Because different dialects cross national boundaries, anthropological linguists become involved in the area where language and politics overlap. Their expertise enables them to discuss language as a system of communication that exists without borders. Dialect studies owe much to Indo-European studies. They first became an interesting area of study because linguists were trying to test the regularity of the sound change laws for Indo-European languages. Rather than accept an early premise that languages were, like biological entities, subject to the laws of evolution, scholars operated under the assumption that languages were organic systems, such that empirical studies could be undertaken to trace regular changes from one dialect area to another.

In the same way, issues surrounding linguistic diversity and social mobility are viewed by anthropological linguists as field situations no different than other field situations. Since language *per se* does not have a value attached, although society may attach a value to certain dialects, anthropological linguistics is able to study and analyze the differences between dialects and often keep antagonistic social responses and social stereotypes from burgeoning. In other words, dialects also have social significance.

Still another aspect of language as communication is what happens between two cultures. When people from two different cultures come into contact and want to or need to communicate there are several possible ways that this can be accomplished:

through sign language; a third language which is common; speakers can be bilingual in the two languages; or a mixed language can develop from the communicative act. This fourth way of communicating is also of special interest to the anthropological linguist.

Pidgins and creoles, which are mixed languages, develop when the status or power of one of the languages and/or its speakers is higher than the other. Pidgins are developed as the native language of none of the speakers. A creole is the native language of a group of speakers and develops from a pidgin when children begin to learn the pidgin as their first language and the vocabulary increases. Pidgins and creoles are also of concern because they can be used to study of the evolution of language.

Changes in a language are systematically connected to changes in the culture of its speakers. Thus, it is not surprising that anthropological linguistics is also concerned with the history of language change and with understanding why there are similarities and differences among all human languages. To achieve this understanding it is necessary to do systematic comparisons among languages. These changes are based on the assumption that changes in one part of the grammar are generalized to other parts of the language. The changes can be anywhere in the grammar, but are often studied in the phonological system, where, for example, changes in the place or manner of articulation occur, sounds are assimilated or dissimilated, or metathesis can take place. Of course, changes in languages can be studied by comparing different languages that seem to be related. We can study the geographic distribution of lexical items or of grammatical elements. We can also look at the grammatical and lexical characteristics of language groups that we are sure are related and see how the languages have diffused. Edward Sapir, in particular, discussed ways in which the analyst could deal with the age of linguistic features. And although he is rarely looked to in contemporary times for his suggestions, they had a significant impact on the study of the geographical distribution of numeral classifiers and classifiers in general.

On the other hand, we should note that many cultures, especially up until the first half of the 20th century, had no writing system and no written histories. And so, once the anthropological linguist had completed a grammar of the contemporary forms of speaking, there was often the challenge of trying to determine what the earlier stages of the language were like. By using the techniques of linguistic reconstruction we have been able to make inferences about earlier stages of a contemporary language. This is possible because it is understood that languages are constantly changing and that these changes occur in a regular systematic way.

The paths of anthropological linguistics also lead to diachronic type of questions. Thus, while studying a language spoken by a very small number of people, the question arises about where the population came from. Were they always in the same geographic territory? When did the group come into existence? Where did their language come from? And then, ultimately, there are questions about the origin of language anywhere. Another issue of interest to anthropological linguists is that of language typologies. One kind of typology is a functional typology of languages based on their evolutionary characteristics. Nineteenth-century scholars classified languages, not along a scale, but rather into three basic groupings: analytic, synthetic, and polysynthetic. Languages whose words consisted of only one morpheme were called analytic. Languages with more than one morpheme per word were considered synthetic (and these were basically the European languages), but then when Native American languages were discovered, languages which had a very high number of morphemes per word, the term 'polysynthetic' was coined. Another type of morphological classification, especially popular in the late 19th century, categorized the languages of the world according to four groups: isolating (a morpheme is also a word, contains one syllable, rarely has affixes), agglutinating (several morphemes combine into one word and may include affixes), inflecting (similar to agglutinating but adds inflection to indicate grammatical functions), and incorporating (the words in a sentence are all fused into one long word). The value of these classifications is limited, but in relative terms, one can talk about some languages being relatively more synthetic than other languages, or more polysynthetic than others. As a result of this typology, many errors have crept into the folklore about languages spoken by peoples whose cultures are thought of as being less advanced than those of the developed part of the world. And so, anthropological linguists analyze the languages of their consultants, not only in terms of describing and explaining the intricacies of those languages, but also to show that all languages are on an evolutionary par, and that every language spoken can discuss any aspect of life in First, Second or Third World cultures, but always in different ways. More recently, a third type of morphological typology has emerged which is based on the order of the grammatical entities of subject (S), verb (V) and object (O).

Because language and human communication is unique, anthropological linguists are especially interested

in human speech acquisition. Children's language learning has been studied by many anthropologists eager to study the stages of acquisition in cultures they themselves are just being introduced to. What appear to be fairly universal are the stages of speech acquisition, but what may be quite different is the relationship between language and cultural acquisition. Children learn that it is very important for them to learn how to use their language and that effective use is crucial to successful communication. For some cultures, child acquisition of the native language is not an important issue, whereas for other cultures, parents and caretakers invest a great deal of time and energy in insuring that the child learns proper verbal etiquette while learning how to speak. Language acquisition and the importance of language in child socialization has long been of interest to anthropological linguists. This is not surprising because as a field linguist one becomes aware of crosscultural trends in the acquisition of communicative competence. The more data one collects, the greater the chance of making significant generalizations about both the process of language acquisition and that of cultural acquisition. Although in large part the study of child language acquisition has been done by psycholinguists, psychologists, neuroscientists, and cognitive scientists, the individual studies done by anthropological linguists as part of their uncovering the grammars of different languages has added considerable data for others to utilize.

Anthropology and Pragmatics

Introduction

To see how anthropology and pragmatics are interrelated, we may start with the following observation: pragmatics concerns, first and foremost, actions and events that necessarily take place in context as actual happenings, that is, sociohistorically contextualized unique happenings. Such happenings, however, may be seen as tokens of virtual regularities such as action types, event types, or even illocutionary types (*see* **Speech Acts**; **Mood, Clause Types, and Illocutionary Force**). Hence, pragmatics may be approached from two different points of departure, either the sociohistoric context or the decontextualized regularities. This condition has given rise to the two distinct scientific traditions dealing with 'what we do' (i.e., our praxis): either the social science of actions and events, such as sociology and anthropology, or the logico-linguistic science of propositionally centered regularities of speech acts. Both of these trends originated in (neo)Kantian philosophy (see later); they may be characterized as the pragmatic and the semantic tradition, respectively (*see* **Kant, Immanuel (1724–1804)**). Note, however, that the term 'pragmatics' is, by historical accident, attached to a branch of the semantic tradition. This tradition includes analytic logic, linguistics, and parts of psychology, anthropology, and pragmatics (e.g., ethnoscience, cognitive linguistics, and the theories of speech acts, implicature, and relevance). In contrast, the pragmatic tradition includes the social sciences, sociology, anthropology, critical philosophy, and parts of contemporary pragmatics such as critical discourse analysis and social pragmatics. In the following sections, the genealogies of these two post-Kantian traditions are elucidated, illustrating how linguistic anthropology is related to pragmatics (*see* **Critical Applied Linguistics**; **Critical Discourse Analysis**; **Cognitive Linguistics**; **Speech Acts**; **Implicature**; **Discourse, Foucauldian Approach**; **Pragmatics: Overview**).

The Semantic Tradition

Let us start with the semantic tradition, which harkens back to the critical philosophy of Kant (1724–1804), in which the problematic of 'language' and 'meaning' still lurked behind that of '(re)cognition' and 'judgment.' The return-to-Kant movement of the late 19th century included not only the neo-Kantians in the narrow sense, such as Charles Peirce (see below), but also Gottlob Frege (1848–1925), who launched predicate logic and thereby started to reduce the (neo) Kantian problematic of 'judgment' and 'value' to questions of logical language (*see* **Peirce, Charles Sanders (1839–1914)**; **Frege, Gottlob (1848–1925)**). In particular, the notion of judgment, especially that of 'synthetic' judgment, became eclipsed by the analytic *Satz* (sentence, proposition), which was split into *Kraft* (e.g., assertoric, imperative, interrogative force) and *Sinn* (propositional content); the latter, again, was subdivided into categories and subcategories that could be characterized in formal-linguistic fashion, such as subject, predicate, and so on (*see* **Chart Parsing and Well-Formed Substring Tables**). Thus was born modern logic (analytic philosophy), to be pursued by Bertrand Russell (1872–1970), Rudolf Carnap (1891–1970), John von Neumann (1903–1957), and others who studied formal-structurally encoded meanings outside the context of language use. Such studies, which later came to include work in Artificial Intelligence, became the main staple of 20th-century Anglophone philosophy. This analytic 'linguistic turn' (Rorty, 1967) was also taken by the linguists of that period, especially the formalists of the neo-Bloomfieldian and Copenhagen Schools (*see* **Bloomfield, Leonard (1887–1949)**. Like the logicians, they saw the essence of language, as well as the essence of the science of language, in formal regularities (rules) and clear and distinct analysis, in a decontextualized environment. Eventually, the trends in logic and linguistics converged and gave rise to generative linguistics, led by Noam Chomsky (b. 1928), who learned neo-Bloomfieldian formalism from Zellig Harris (1909–1992) and logico-linguistic derivation from Carnap. Even granted that Carnap was an empiricist, like Charles Morris (see below)

Introduction

To see how anthropology and pragmatics are interrelated, we may start with the following observation: pragmatics concerns, first and foremost, actions and events that necessarily take place in context as actual happenings, that is, sociohistorically contextualized unique happenings. Such happenings, however, may be seen as tokens of virtual regularities such as action types, event types, or even illocutionary types (*see* **Speech Acts**; **Mood, Clause Types, and Illocutionary Force**). Hence, pragmatics may be approached from two different points of departure, either the sociohistoric context or the decontextualized regularities. This condition has given rise to the two distinct scientific traditions dealing with 'what we do' (i.e., our praxis): either the social science of actions and events, such as sociology and anthropology, or the logico-linguistic science of propositionally centered regularities of speech acts. Both of these trends originated in (neo)Kantian philosophy (see later); they may be characterized as the pragmatic and the semantic tradition, respectively (*see* **Kant, Immanuel (1724–1804)**). Note, however, that the term 'pragmatics' is, by historical accident, attached to a branch of the semantic tradition. This tradition includes analytic logic, linguistics, and parts of psychology, anthropology, and pragmatics (e.g., ethnoscience, cognitive linguistics, and the theories of speech acts, implicature, and relevance). In contrast, the pragmatic tradition includes the social sciences, sociology, anthropology, critical philosophy, and parts of contemporary pragmatics such as critical discourse analysis and social pragmatics. In the following sections, the genealogies of these two post-Kantian traditions are elucidated, illustrating how linguistic anthropology is related to pragmatics (*see* **Critical Applied Linguistics**; **Critical Discourse Analysis**; **Cognitive Linguistics**; **Speech Acts**; **Implicature**; **Discourse, Foucauldian Approach**; **Pragmatics: Overview**).

The Semantic Tradition

Let us start with the semantic tradition, which harkens back to the critical philosophy of Kant (1724–1804), in which the problematic of 'language' and 'meaning' still lurked behind that of '(re)cognition' and 'judgment.' The return-to-Kant movement of the late 19th century included not only the neo-Kantians in the narrow sense, such as Charles Peirce (see below), but also Gottlob Frege (1848–1925), who launched predicate logic and thereby started to reduce the (neo) Kantian problematic of 'judgment' and 'value' to questions of logical language (*see* **Peirce, Charles Sanders (1839–1914)**; **Frege, Gottlob (1848–1925)**). In particular, the notion of judgment, especially that of 'synthetic' judgment, became eclipsed by the analytic *Satz* (sentence, proposition), which was split into *Kraft* (e.g., assertoric, imperative, interrogative force) and *Sinn* (propositional content); the latter, again, was subdivided into categories and subcategories that could be characterized in formal-linguistic fashion, such as subject, predicate, and so on (*see* **Chart Parsing and Well-Formed Substring Tables**). Thus was born modern logic (analytic philosophy), to be pursued by Bertrand Russell (1872–1970), Rudolf Carnap (1891–1970), John von Neumann (1903–1957), and others who studied formal-structurally encoded meanings outside the context of language use. Such studies, which later came to include work in Artificial Intelligence, became the main staple of 20th-century Anglophone philosophy. This analytic 'linguistic turn' (Rorty, 1967) was also taken by the linguists of that period, especially the formalists of the neo-Bloomfieldian and Copenhagen Schools (*see* **Bloomfield, Leonard (1887–1949)**. Like the logicians, they saw the essence of language, as well as the essence of the science of language, in formal regularities (rules) and clear and distinct analysis, in a decontextualized environment. Eventually, the trends in logic and linguistics converged and gave rise to generative linguistics, led by Noam Chomsky (b. 1928), who learned neo-Bloomfieldian formalism from Zellig Harris (1909–1992) and logico-linguistic derivation from Carnap. Even granted that Carnap was an empiricist, like Charles Morris (see below)

and Willard Quine (1908–2000), whereas Chomsky worked in a rationalist paradigm, these philosophers and linguists represented two sides of the same semantic tradition. Subsequently, with the success of what became known as the Chomskyan revolution, the dominance of the semantic tradition in linguistics and its subfields was confirmed in the 1960s (*see* **Chomsky, Noam (b. 1928); Quine, Willard van Orman (1908–2000)**).

Yet, this 'revolution' was just an evolution of an earlier condition. That is, in tandem with the advocates of 'unified science' such as Carnap and Morris, who tried to integrate all kinds of science on the basis of modern formal logic, using the method of modern physics, the neo-Bloomfieldians had elaborated and advanced a linguistic formalism that was meant to replace the humanistic, cosmographic concerns of philology and anthropological linguistics with the investigation into the formal regularities of language and mechanical analytic procedures. Doing this, they successfully turned linguistics into a model human science in the eyes of many. Thus, the semantic tradition evolved from logico-linguistics into the more empirical sciences of anthropology and cognitive psychology. As an instance, consider the mid-20th-century flourishing of ethnoscience, which was characterized by mechanical elicitation procedures, with anthropologists trying to identify the semantic categories of fauna, flora, kinship, color, etc., as emically apperceived by natives and etically described by 'universal' semantic categories (*see* **Ethnoscience**). Eventually, ethnoscientific studies – such as those of color terms conducted by Berlin and Kay (1969), who were originally inspired by the Saussurean/Hjelmslevian formal-structural analysis – yielded to the more empirically oriented 'prototype' semantics developed by Eleanor Rosch and her school in the 1970s (cf., Blount, 1995). Similar empiricist orientations gained acceptance even in logic and linguistics; compare the rise of fuzzy logic (or, more generally, multivalued logic) and generative semantics. The three lines then converged to form cognitive linguistics, pursued by George Lakoff (b. 1941), Ronald Langacker (b. 1942), and their followers. Thus, the birth of an empirical semantic science, i.e., cognitive linguistics, which constitutes a branch of pragmatics today, has its origin in the Fregean analysis of decontextualized propositional content (*Sinn*), which gradually, yet increasingly, became accommodated to the empirical contexts of referential cognition and language use (*Bedeutung*).

But the Fregean legacy includes more. Recall that Frege reduced judgment to sentence, consisting of not only propositional content, but also force. This notion came to the attention of John Austin (1911–1960), a phenomenologically minded translator of Frege's *œuvre* into English (compare Frege's notions of propositional content vs. force with Austin's notions of constative vs. performative and locution vs. per-/illocution) (*see* **Austin, John Langshaw (1911–1960); Mood, Clause Types, and Illocutionary Force; Speech Acts and Grammar**). This move led to the emergence of what is often called modern pragmatics, as pursued by John Searle and his followers (formally, this trend can be captured by the expression F(p), where p and F stand for proposition and illocutionary force, respectively). Others, such as H. Paul Grice (cf. 'what is said' vs. 'what is meant') and the post- and neo-Griceans, followed suit (cf. the success of Daniel Sperber and Deirdre Wilson's theory of relevance) (*see* **Grice, Herbert Paul (1913–1988); Neo-Gricean Pragmatics; Relevance Theory**). Clearly, this post-Fregean trend also belongs to the semantic tradition and constitutes, with cognitive linguistics, its empirical development (*see* **Cognitive Linguistics**) Notwithstanding the label 'pragmatics' that is commonly attached to it, this trend is little more than a branch of empirical semantics, inasmuch as it attempts (as do cognitive linguistics and linguistic functionalism) to relate, if not reduce, the meanings encoded in language (i.e., in lexico-grammar: sentence, clause, phrase; words, clitics, and morphemes) to empirical matters such as function, language use, and understanding. This brand of pragmatics thus excludes such contextual phenomena as cannot be transparently related to propositional meanings or grammatical rules; that is, most human practices, which occur contingently and largely independently of linguistically encoded meanings (cf. Mey, 2001).

In this connection, the following three points are worth observing: (1) the grammarians called 'generative semanticists,' such as George Lakoff and James McCawley, found post-Austinean pragmatics useful; (2) Dan Sperber and Deirdre Wilson's (neo)-Gricean relevance theory remains a highly abstract account based on *a priori* assumptions (economy, eufunctionalism, cooperation, and logico-rationalistic computation), while remaining impervious to the contextual and historic contingencies that lie at the heart of matters pragmatic; and finally (3) the current popularity of trends such as relevance theory and cognitive linguistics may be in part due to their eclectic, quasi-pragmatic, and quasi-semantic character, in line with their emergence at the transitional point where contemporary pragmatics is moving from more semantically oriented theories (such as those of speech acts or generative semantics), which are primarily concerned with linguistically encoded meanings, toward more robustly pragmatic theories, such as social pragmatics and critical discourse analysis, which are primarily concerned with contingent actual happenings in a

sociohistorical context (*see* **Speech Acts; Generative Semantics; Critical Discourse Analysis; Pragmatics: Overview**).

Thus far, we have seen how the two post-Fregean semantic trends have led to cognitive linguistics and pragmatics. In the following discussions, we follow the genealogy of a nonsemantic, yet truly pragmatic tradition, derived not from Frege, but from other neo-Kantians, such as Peirce, Franz Boas, and Max Weber, and ultimately going back to Kant himself.

The Social-Scientific Tradition of Pragmatics

The genuinely pragmatic tradition, often known as the social sciences, includes anthropology and sociology, the origin of which goes back to Bronislaw Malinowski (1884–1942), Weber (1864–1920), Georg Simmel (1858–1918), Emile Durkheim (1858–1917), Boas (1858–1942), Karl Marx (1818–1883), Alexander Humboldt (1769–1859), and ultimately the Enlightenment philosophers such as the Marquis de Condorcet (1743–1794), Voltaire (1694–1778), and perhaps even the earlier Giambattista Vico (1668–1744). However, the most important figure in the current discussion is Johann Herder (1744–1803), a student of Kant who critically accepted Kant's critical philosophy and, in doing this, launched a metacritique of the latter, especially of its claim to human (and even 'anthropological' – the term is Kant's own) universality. In Herder's view, such alleged universality is no more than an ideology, conditioned by the historic, geographic, and cultural (that is, contextual) factors peculiar to the Idealist philosopher Kant and his times, i.e., the modern era of the German (secularized Lutheran) Enlightenment. Note that the idea of metacritique was already contained in Kant's critical philosophy, which tried to show, at the transcendental (second-order, or meta-) level, the valid limits of all philosophizing, including its own. Herder in turn elaborated on this theme, attacking Kant's claim to universality by appealing to the cultural diversity of the empirical world(s). Since the validity of such a metacritique can be assessed only by actual investigations into the empirical world, Herder's move led to the birth of the modern social sciences, especially in Germany, as attested by the works of Marx, Boas, and Weber, in which various eras and cultures were methodically compared. In so doing, these authors interpretively identified the sociohistoric uniqueness and contingent conditions of particular cultures and periods and demonstrated the historic/cultural limits and relativity of modern western thought and its 'products' (including the social sciences and their ethnocentric universalism). Such was the underlying theme of Boasian anthropology, to be described shortly, following a brief look at the development of the 'new' science of sociology (*see* **Boas, Franz (1858–1942)**).

In the 19th century, between Kant's and Durkheim's times, rapid modernization, urban immigration, and capital formation progressed in England, France, and then Germany, leading to the emergence of social problems such as dire poverty, overpopulation in urban environments, and terrifying labor conditions. As the masses came into being in cities, society became a visible entity, to be investigated through demographic, statistical, and analytical means by reformers in the spirit of Henri de Saint-Simon (1760–1825) and scholars such as Auguste Comte (1798–1857) and Durkheim himself, who created a science called 'social physics' (which later became sociology) to measure, analyze, and control (i.e., 'tame') the social problems. Henceforth, sociology would develop around the two axes of Weberian interpretive, historical sociology (see earlier) and Durkheimian functionalist or statistical macrosociology. However, in the Anglophone world, the latter axis was much stronger, compared to the European continent; this can be seen exemplified in the works of British structural functionalism (social anthropology) and in Talcott Parsons's (1902–1979) systemic sociology in the United States. Such was the contextual background of what came to be known as, on the one hand, the sociology of language, as practiced by scholars such as Joshua Fishman, Charles Ferguson, and others (cf., Giglioli, 1972), and as, on the other hand, Labovian sociolinguistics (*see* **Labov, William (b. 1927)**); the latter squarely belonged to the mainstream Anglophone tradition of structural-functional sociology, giving preference to macrosocial facts and regularities over interpretations and microsocial, contingent happenings.

In conflict with the latter tradition, the sociologist Erving Goffman (1922–1982) paved the way for a minute descriptive analysis of the dynamics of discourse at the microsocial level, and thus helped to revive the interpretive sociology of Weber, Simmel, Edward Sapir (1884–1939), G. H. Mead (1863–1931), and the Chicago School of sociology, known for its ethnographic and symbolic-interactional approaches (cf. Blount, 1995). This revival, often called the 'hermeneutic turn,' came to put its mark on various social sciences, including cultural anthropology, where Clifford Geertz (b. 1926), in the mid-1970s, successfully criticized the semantic orientation of ethnoscience (see earlier) for its neglect of interpretation and context. Similarly, in sociology, the phenomenological movement developed in the wake of the German sociologist Alfred Schutz's (1899–1959) works represented a long-awaited renaissance in ethnomethodology, originally advanced by Harold

Garfinkel (b. 1917), who tried to base the entirety of sociology on the microsocial phenomena of lived worlds, especially their everyday interpretations and dynamic contextualization. Yet, the positivist standard of formal rigor and the phobia of interpretive ambiguity in sociology were such that ethnomethodology quickly lost its contextual flexibility, critical reflexivity, and comprehensive scope, and underwent formalization and miniaturization, thus turning into an independent sociological practice, namely, conversation analysis. This school (often thought to be associated with pragmatics) subsequently incorporated some of Goffman's insights and ideas of post-Fregean pragmatics, as evidenced in Penelope Brown and Stephen Levinson's types of conversational activity and theories of polite behavior (considered as face-maximizing rational decision-making). These theories, due to their eclectic nature, enjoyed popular acclaim especially during the transitory phase when modern pragmatics moved from the semantic to the social-scientific tradition, i.e., in the late 1970s and early 1980s (*see* **Activity Theory**; **Face**; **Politeness**).

The preceding discussion outlines a general genealogy of the microsociological theories of pragmatics. Yet, as regards the crux of the social-scientific tradition, which can be said to lie in the exploration of the sociocultural mechanisms by which language contextually indexes power relations, authorities, and identities, it is missing in most of these theories. In contrast, there are Goffman's microsocial analyses of interaction ritual, frame, and symbolic self-presentation later incorporated into the French sociologist Pierre Bourdieu's (1930–2002) macrosocial theory of 'reproduction through habitus,' the field of practice, and symbolic capital. In Britain's class-stratified society, Basil Bernstein (1924–2000) also struggled with this problematic, especially when it came to determining the role that language plays in formal education. These three figures thus anticipated the coming of a truly social-scientific kind of pragmatics, i.e., critical pragmatics, as pursued in the 1980s by social semioticians, by Norman Fairclough and his Lancaster School, and others, such as Mey (1985, 2001), whose works share more and more traits with the paradigm elaborated by the anthropological tradition (*see* **Codes, Elaborated and Restricted (Bernstein)**; **Social Semiotics**).

Although the above-mentioned groups have distinct genealogies, networks, and theoretical foci, all of them are nonetheless actively engaged in the social critique of language in education, medicine, and other kinds of controlling social instances; they also share among them many sources of critical inspiration and much theoretical weaponry, including the works of Peirce, Boas, Sapir, Benjamin Whorf, Roman Jakobson, Dell Hymes, and John Gumperz in North America (see later), as well as the traditions embodied in the writings of Malinowski, J. R. Firth, M. A. K. Halliday, Raymond Williams, E. P. Thompson, and Stuart Hall in Britain; Émile Benveniste, Roland Barthes, Louis Althusser, Jacques Derrida, Michel Foucault, and Gilles Deleuze in France; Marx, Weber, Theodor Adorno, Walter Benjamin, and Jürgen Habermas in Germany; Antonio Gramsci in Italy; and Mikhail Bakhtin and Valentin Voloshinov in the former Soviet Union. All of these traditions can be seen as unified from a social-scientific perspective, focusing on language use as discourse, i.e., language in social context, and seeing pragmatics, located at the core of language, as praxis, involving social conflicts, power struggles, and identity (re)formations (*see* **Austin, John Langshaw (1911–1960)**; **Foucault, Michel (1926–1984)**; **Grammatology**). And, if pragmatics is worthless unless it is concerned with contextualized linguistic practice, that is, with what is done by peoples and individuals living in particular societies and particular times – i.e., not just with 'what is said' (linguistic meaning), but with 'what is done' in a contextually situated, sociohistorical practice – then a genuine pragmatics must be a social science of praxis, of actions and events in culture, society, and history. Such a pragmatics has been emerging since the 1980s; it erases the disciplinary division between linguistic anthropology and pragmatics and enables seeing classic, post-Austinean pragmatics as a transitory phenomenon in the historic drift moving from the semantic tradition, or the logico-linguistics of decontextualized regularities, toward the genuinely pragmatic social science of contextualized actions and events (*see* **Pragmatic Acts**).

In the following sections, we take a genealogical look at the North American 'cosmographic' school of linguistic anthropology, starting with Boas, in order to get a better idea of the social-scientific tradition, where, if the current drift continues, the future of pragmatics lies. We start out with Peirce, the neo-Kantian whose semiotic Pragmati(ci)sm was comprehensive enough to bridge the gap between the Fregean semantic and Boasian anthropological traditions, as witnessed by Jakobson's (1896–1982) synthesis of the two trends under the rubric of Peircean semiotics (*see* **Jakobson, Roman (1896–1982)**).

Pragmatics, Pragmati(ci)sm, and the Social Semiotics of Praxis

As is well known, the term 'pragmatics' has come from a tradition that is located in between semantics and social science, namely, American Pragmati(ci)sm.

In Charles Morris's (1901–1979) triadic formulation, we speak of syntax (form), semantics (meaning), and pragmatics (context) – terms that are derived from the semiotic Pragmati(ci)sm of the neo-Kantian Peirce (1839–1914) and thus properly indicate the origin of pragmatics as being located in Kant's second *Critique*, or more generally, in the latter's critical philosophy.

Peirce, who shared much with other neo-Kantians (such as the phenomenologists), articulated what he called a semiotic 'phaneroscopy' (phenomenology), in which actions and events constitute the basis of knowledge, aesthetics, and historic evolution (teleology). Most importantly, actions and events are signs that point to objects in context, such as agents (stimuli) and experiencers. Therefore, the basic mode of signification is indexicality, which is based on the principle of contextual contiguity; the other empirically oriented mode of signification, iconicity, is based on the principle of contextual similarity between signs and their objects. In addition, there are empirically unmotivated, albeit contextually indexed and/or iconically signaled, kinds of signs, i.e., symbols; these comprise conventional ideas (ideologies) and denotational codes, as they are presupposed by the speech participants involved in actions and events. These three kinds of signs interact with one another to constitute the human cosmology, as it is anchored on the (inter)actions and events taking place at the *hic et nunc* of human activity.

Eventually, this cosmographic theory of signs was adopted by Jakobson, who, in his comprehensive theory of communication (cf., Jakobson, 1990; Lee, 1997), articulated the empirical, indexically anchored universal matrix of grammatical categories and distinctive features, envisioned as the systematic interlocking of symbolic (formal and semantic) *langue* and indexical (phonetic and pragmatic) *parole* (*see* **Jakobson, Roman (1896–1982)**). The Jakobsonian legacy successfully integrated Peircean semiotics and Boasian linguistic anthropology; it has been the guiding thread of North American linguistic anthropology ever since, from Hymes's ethnography of speaking all the way to Michael Silverstein's social semiotics (cf. Blount, 1995). In the beginning, however, there was Boas, to whom we now turn.

The Genealogy of Linguistic Anthropology: The Boasian Cosmographic Tradition

We now try to reconstruct the cosmographic theories due to Boas, Sapir, and Whorf; these early 20th-century theories have become somewhat obscured by the hegemonic dominance of the semantic tradition in linguistics and anthropology, which gained strength in mid-20th century.

As already noted, like Peirce, Boas was a neo-Kantian who had come to understand the human mind in terms of the three processes of similarity, contiguity, and abstraction, in close resemblance with the Peircean triad of iconicity, indexicality, and symbolicity. Unlike Peirce, however, Boas was a social scientist who fought evolutionism and institutionalized racism. In these efforts, he undertook the task of showing the existence of grammatical structures in every known language, especially (Native) American languages, and used his findings to prove the universality of a symbolic "faculty of forming abstract ideas" (Blount, 1995: 26), common to all human beings. In the process, Boas moved on to empirical studies of diverse languages in a universal framework, including hypothetical universal grammar.

Boas came close to discovering the notion of the phoneme, which harkens back, via the German *Völkerpsychologen* such as Heymann Steinthal (1823–1899), to Wilhelm von Humboldt's (1767–1835) idea of *innere Sprachform* and, ultimately, to Kant's notion of 'the inner and formative power of life forms,' as he articulated it in his third *Critique*. Coming to the cultural, idiographic, or cosmographic sciences (in the sense of Alexander Humboldt) such as geography, anthropology, and linguistics, from a background in nomothetic sciences such as (psycho)physics and experimental psychology (cf., Stocking, 1996: 9–16), Boas was naturally impressed by the diversity of human phenomena he observed in culturally and historically situated contexts. He saw the two kinds of sciences as being connected via the faculty of categorical perception, i.e., the human capacity and tendency to impose categorical forms (such as sound patterns) on empirical substance or diverse unique (idiographic) phenomena (such as phones and sensations). In this, Boas anticipated 20th-century structuralism, phenomenology, and Gestalt psychology, and their practitioners, whose battle-cry against 19th-century positivists' preoccupation with sensations was precisely 'the primacy of (categorical) human (ap)perception.' Moreover, and perhaps more importantly, Boas (as did the later structuralists) maintained that linguistic perceptions were decisively conditioned by the unconscious structure of the mind; moreover, this unconscious structure could, no less importantly, be rigorously investigated using a set of techniques not uncritically adopted from the physical sciences, in what came to be called 'structural analysis' (cf., Boas, 1989: 72–77; Sapir, 1949: 166).

Boas understood categorical phonemic perception essentially as a linguistic, structurally and unconsciously conditioned distortion in the conscious perception of phonetic and pragmatic (i.e., empirical)

phenomena. In his critique of logico-linguistic reason (of the kind earlier articulated by Herder and Max Müller (1823–1900), and later by Ludwig Wittgenstein (1889–1951)), Boas made a critical empiricist departure from the Cartesian understanding of the mind, centered around the conscious reflection that rationalists were considered to be the key to the reality and verity. Boas stressed the value of empirical data (i.e., phonetic representations and unadulterated texts), gathered through fieldwork, as being critically important to his effort to show the relativistic plurality of cultures and the invalidity of the *a priori* armchair theories of Eurocentric universalism and rationalism, especially evolutionism (cf., Stocking, 1982: 195–233, 1996: 215–256).

Boas indeed was able to show that similar processes of rationalization underlay both evolutionist reasoning and what was called the primitive, 'savage mind' (cf., Lévi-Strauss, 1962), and hypothesized that such pragmatic processes of conscious rationalization (as opposed to universally valid, logico-semantic reason) were similar across diverse cultures, although their specific contents (which could be empirically investigated through the study of cultural myths and folklore, including modern sciences and philosophy) varied cross-culturally and showed distinct, so-called 'geniuses' of peoples. Thus, Boas, as Marx had done before him, understood theoretical reason and consciousness as a veil, or a mirror that produced distorted reflections of empirical phenomena such as cultural practices. For Boas, conscious behaviors distort and change these practices, which are otherwise unconsciously and habitually carried out and historically preserved. It is in this context that Boas underlined the methodological significance of linguistic structure, a largely unconscious phenomenon, which was assumed to provide a crucial key to the historical reconstruction of past practices (see Blount, 1995: 23–26; cf., Sapir, 1949: 432–433; Silverstein, 1979).

It may be useful to further unfold Boas's argument, in particular as it was later elaborated by Sapir (1949: 26–27, 156). First, both conscious and unconscious elements of the human mind are theorized as essentially reactive in relation to the sociohistorical practices (pragmatics) that are represented by, and give rise to, them. Yet, the agentive awareness (consciousness) of practices is limited, and when human agents act in accordance with such limited and distorted awareness, they precipitate the transformation of these very practices, and history starts unfolding (in Weberian terms, this is the dialectics between conscious ideology, such as Protestant ethic, and actual practice, such as capital formation and labor). On the other hand, the unconscious mind, which comprises linguistic structure, more transparently reflects human practices (at time t_0); but, since practices quickly change, along with consciousness, in a dialectic movement, the unconscious is left behind (at time t_1), and the correspondence with synchronic practices (at t_1) becomes opaque, even though it remains more transparently related to the diachronically prior practices (at t_0). Therefore, both consciousness and the unconscious (where linguistic structure is mostly located) end up being only opaquely related to synchronic practices. Thus, for Boas and his followers, 'synchronic structure' is both synchronic (inasmuch as it is used 'here and now') and diachronic (inasmuch as it points to past practices). This synchrony is made up of both static and dynamic facets, the former (i.e., linguistic structure) relatively transparently pointing to the past and the latter being 'where the action is' (viz., pragmatics and phonetics); the Weberian dialectic interaction between the two, contingently creates the historic conditions for the structures and actions that are yet to come (*see* **Phonetics and Pragmatics**). Thus, the discovery of the phoneme (and of linguistic structure in general) was directly linked to the rebuttal of 19th-century neogrammarians' genetico-causal determinism (itself a further derivate of the Newtonian–Laplacean deterministic worldview), according to which the posterior condition is mechanically determined by the anterior, and faultlessly derivable from it. The discovery of synchrony (vs. achrony) also was instrumental in Saussure's discovery of the historic dialectics of *langue* and *parole* (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913)**), as noted by the dialectician Maurice Merleau-Ponty (1908–1961), who properly stressed the importance of the latter's discovery of *parole* (and, implicitly, of pragmatics).

No less important, given the opacity between structure and practice in the synchronic phase, is the following corollary: from the preceding premises, it deducibly follows that phonetic acts do not transparently match the phonemic categories they correspond to – a mismatch that provides part of the conditions 'distorting' phonemic apperceptions. Similarly, pragmatic acts (say, commands) do not uniquely match grammatical categories (say, the imperative mood, as becomes clear when we study the so-called indirect speech acts) (*see* **Pragmatic Acts**). In other words, the irreducibility of linguistic structure to pragmatics, a phenomenon that Chomsky sees as having its origin in the human innate faculty of reason, is shown to be deducible as a consequence of historical dialectics, generated by the very limits of consciousness or reason (cf., Sapir, 1949: 100–103). Further, just as phonetic phenomena are misperceived through our unconscious phonemic patterning (which escapes reason), pragmatic practices and referents are often incorrectly apperceived by the native mind due to an unconscious grammatical patterning (that is, due to

the language-specific structural pattern found to exist in the morphosyntactic encoding of grammatical categories) (*see* **Speech Acts and Grammar**). This is the crux of the argument that has come to be known as the linguistic relativity hypothesis (cf., Blount, 1995: 26–28; Cowan *et al.*, 1986: 455–477; Whorf, 1956: 134–159) (*see* **Sapir, Edward (1884–1939); Whorf, Benjamin Lee (1897–1941)**).

Examining the linguistic relativity hypothesis requires us to undertake empirical studies of linguistic structures and practices across languages and cultures, which again necessitates the hypothetical construction of universal inventories of structurally significant sounds and grammatical categories (as these indeed were presented by Boas (1911)). Clearly, the typological works of Sapir (1921) and Whorf (1956: 87–101) – as well as Jakobson's (1990) theories of distinctive features and verbal categories, which may be marked 'overtly' or 'covertly' (Whorf, 1956: 87–101) in particular languages – were further elaborations of this non-Eurocentric 'universal grammar,' based on emically significant categories in the languages of the world, and suggesting the possible existence of a universal human reality underlying the particular worlds of diverse cultures (cf., Sapir, 1949: 160–166; Whorf, 1956: 147, 207–232).

The basic framework of the Boasian cosmographic tradition, as it was shared by Sapir and Whorf, became the context in which Sapir's twin notions of drift and psychological reality are to be understood. That is, in contradistinction to the neogrammarians' mechanical, genetico-causal 'blind change,' drift, vaguely and holistically perceived as *Sprachgefühl*, refers to historical structural changes caused by the dialectic interaction between structure, language use, nonlinguistic practice, and metalinguistic rationalization. Sapir, a social scientist, understood that ideal patterns (Sapir, 1921: 147; 1949: 23, 83–88, 533–543) in structure were necessarily realized not in their pure forms, but in contextualized and varied, i.e., idio-, dia-, and sociolectal, form-tokens. Some of these variations may become saliently social-indexical and directly involved in the social struggles for cultural hegemonies, as well as in processes of normative rationalizations. In such cases, the interaction between language and society often results in structural changes (cf., Blount, 1995: 513–550). Also, some of the variations may become privileged when language users feel they are being formally correct, that is, actualizing potential regularities implicitly suggested by the synchronic state of language. In such a case, the variations analogically deducible from the structure's dominant pattern may become part of the structure that will arise from the interaction between language and the *Sprachgefühl* of the language users (cf., Sapir, 1921: 147–191; Whorf, 1956: 134–159; Lucy, 1992). (Sapir hypothesized in addition that such analogies were drawn and actually implemented because of unconscious human strivings for formal beauty; on this, see below.)

Sapir's (1949: 16, 33–60) 'psychological reality' may be similarly reconstructed in the following way. Sapir (1949: 433) started out from the Boasian thesis that linguistic consciousness was opaque to practices, partly because it was influenced by unconscious structural (sound) patterns. This implies, Sapir noted, that there is some transparent linkage between consciousness and 'inner forms' (the sound patterns). Of course, native language users cannot consciously articulate the structure of their language, but they can 'feel,' half- or sub-consciously, such inner forms, which are beyond the realm of phonetic behaviors directly perceived by outsiders of the linguistic community. In other words, native language users (insiders) 'click with' (Sapir, 1949: 48, 159) the linguistic structure at the intersection of their consciousness and unconscious, i.e., at the level of feelings. And such an inarticulate, yet immediately sensed *Sprachgefühl*, and with it, the unconscious structural patterns, are manifested even in overt linguistic behaviors such as the categorical apperceptions of sounds, actions, and referents (cf., Sapir, 1921: 55, 1949: 46–60, 150–159; Whorf, 1956: 134–159). These attested behaviors would remain unexplained if it were not for the phenomenological reality of the phoneme and other form-patterns in the unconscious. Moreover, Sapir noted that allophones of a phoneme often historically developed into different phonemes. In his view, this meant that phonemic inner forms often transparently correspond to the historically reconstructed phonetic (allophonic) behaviors of users in the past (cf., Cowan *et al.*, 1986: 67–106). In this way, the linguistic history of a community was discovered to be alive (phenomenologically, psychologically real, or 'organic') in the *Sprachgefühl* and innermost unconscious of the language users. The individual mind, in short, is communal and historical in its subconscious core. Hence, Sapir noted, there is no need to oppose the individual to the social (collective), to hypostatize a 'super-organic' collectivity existing independently of individuals, or to reify culture or language.

In Sapir's cosmographic theory, the psychological reality had other important implications for the cultural nature of the human mind. That is, unconscious, historical, and communal symbolic forms are ideologically projected onto the chaotic reality of discursive practices, precipitating the chaotic, rhapsodic, and romantic "flux of things into tangible forms, beautiful and sufficient to themselves" (Sapir,

1949: 348), as they are found in poetically structured discursive texts and rituals. In and by themselves, the symbolic forms constitute an artwork of classicism, often referred to as 'the poetry of grammar,' created by the human striving for an aesthetic totality, *un système où tout se tient* (compare the notion of drift, referred to previously) (cf., Sapir, 1949: 344; Cowan *et al.*, 1986: 455–477; also consider Jakobson's (1990) 'poetic function'). Thus, in Sapir's view, the very regularity of linguistic structure – a regularity necessary in order to operate with decontextualized denotational and cognitive significations – is constituted by our aesthetic, expressive, and ideological strivings for formal completeness. Cognition, aesthetics, emotion, history, society, and the individual are thus intertwined in Sapir's cosmographic theory.

Unfortunately, the inroads made during the 1940s and 1950s by the semantic tradition into the sciences of language almost altogether eclipsed Sapir's cosmographic science, except in the narrow circle of linguistic anthropologists. This process started with the neo-Bloomfieldians, to be followed by the ethnoscientists in anthropology, the Chomskyans in (psycho)linguistics, and the cognitive scientists of diverse obediences, who all operated in this tradition. Nevertheless, Sapir's students, such as Stanley Newman (1905–1984) and Mary Haas (1910–1996), successfully passed the torch to the next generation, whose representatives included John Gumperz and Dell Hymes, who succeeded in firmly integrating the Boasian and Peircean–Jakobsonian (semiotic) approaches (cf., Gumperz and Hymes, 1986). Subsequently, Hymes's theory of communication, called the 'ethnography of speaking,' gained momentum in the 1970s (cf., Bauman and Sherzer, 1974), a decade that saw the hermeneutic (i.e., interpretive, contextual, or (neo-)pragmatic) turn in the social sciences and Anglophone philosophy (as pointed out previously). This turn provided the historic conditions for a revival of the Boasian tradition in contemporary North American linguistic anthropology, locating language squarely at the intersection of history, ideology, and practice (see Blount, 1995; Brenneis and Macaulay, 1996; Duranti, 2001; Kroskrity, 2000; Lee, 1997; Lucy, 1992, 1993; Schieffelin *et al.*, 1998; Silverstein and Urban, 1996). Here, the historic, ideological, and pragmatic aspects of language, including not only grammar, but also (con)textualization, language change and variation, Bakhtinian voicing, standardization, rationalization, modernization, linguistic nationalism and imperialism, language purism, feminism and gender, literalism, and other cultural ideologies and practices, seen in their sociohistoric context, are cosmographically studied in a social-scientific framework. Their discovery of the (re)formations of group identities and power relations and sociocultural conflicts as happening in, and being constituted by, language as the central element thus converges with the social drift of contemporary critical pragmatics.

Anthroposemiotics

A Ponzio, University of Bari, Bari, Italy

© 2006 Elsevier Ltd. All rights reserved.

Anthroposemiotics is the science that studies the 'semiotic animal,' i.e., man. The semiotic animal is not only capable of using signs (i.e., of semiosis), but also of reflecting on signs through signs.

Anthroposemiotics today has freed itself from two traditional limitations: 'anthropocentrism' and 'glottocentrism.'

With regard to the first, anthroposemiotics does not coincide with general semiotics, but is a part of it. Semiotics is far broader than a science that studies signs solely in the sphere of socio-cultural life. Semiotics also studies the signs of unintentional communication (semiology of signification); before this, it was limited by exclusive preference for the signs of intentional communication, Saussure's *sémiologie* (semiology of communication). In contrast, semiotics following Thomas A. Sebeok and his 'global semiotics' studies communication not only in culture, but also in the universe of life generally. From this perspective, biosemiotics provides the broader context for anthroposemiotics or semiotics of culture and is not separate from the latter. Anthroposemiosis as a cultural process is at the intersection between nature and culture.

With regard to the second aspect, getting free from glottocentrism, critique of glottocentrism in anthroposemiotics must be extended to all those trends in semiotics that refer to linguistics for their sign model. Anthroposemiotics insists on the autonomy of nonverbal sign systems from the verbal and also studies human sign systems that depend on the verbal only in part, despite the prejudicial claim that verbal language predominates in the sphere of anthroposemiosis.

To get free from the anthropocentric and glottocentric perspective as it has characterized semiotics generally, implies taking other sign systems into account beyond those specific to mankind. These signs are not alien to the human world, but they are not specific to it. They concern the encounter between human communication and the communicative behavior of non-human communities and with the environment; they also concern the sphere of endosemiotics, cybernetic systems inside the body on both the ontogenetic and phylogenetic level.

Anthroposemiotics now avoids biologism that occurs when human culture is reduced to communication systems traceable in other species, just as it avoids the anthropomorphic reduction of nonhuman animal communication to distinctive features and models specific to mankind.

Anthroposemiotics focuses on signs studied by specialists from different fields, viewing them at once in their specificity and interrelationship. These signs range from the signs of 'nature' to the signs of 'culture,' from verbal signs to nonverbal signs, from natural languages to artificial languages, from highly plurivocal and dialogical signs to univocal and monological signs, or better signals, signs endowed with varying degrees of indexicality, symbolicity, and

Anthroposemiotics is the science that studies the 'semiotic animal,' i.e., man. The semiotic animal is not only capable of using signs (i.e., of semiosis), but also of reflecting on signs through signs.

Anthroposemiotics today has freed itself from two traditional limitations: 'anthropocentrism' and 'glottocentrism.'

With regard to the first, anthroposemiotics does not coincide with general semiotics, but is a part of it. Semiotics is far broader than a science that studies signs solely in the sphere of socio-cultural life. Semiotics also studies the signs of unintentional communication (semiology of signification); before this, it was limited by exclusive preference for the signs of intentional communication, Saussure's *sémiologie* (semiology of communication). In contrast, semiotics following Thomas A. Sebeok and his 'global semiotics' studies communication not only in culture, but also in the universe of life generally. From this perspective, biosemiotics provides the broader context for anthroposemiotics or semiotics of culture and is not separate from the latter. Anthroposemiosis as a cultural process is at the intersection between nature and culture.

With regard to the second aspect, getting free from glottocentrism, critique of glottocentrism in anthroposemiotics must be extended to all those trends in semiotics that refer to linguistics for their sign model. Anthroposemiotics insists on the autonomy of nonverbal sign systems from the verbal and also studies human sign systems that depend on the verbal only in part, despite the prejudicial claim that verbal language predominates in the sphere of anthroposemiosis.

To get free from the anthropocentric and glottocentric perspective as it has characterized semiotics generally, implies taking other sign systems into account beyond those specific to mankind. These signs are not alien to the human world, but they are not specific to it. They concern the encounter between human communication and the communicative behavior of non-human communities and with the environment; they also concern the sphere of endosemiotics, cybernetic systems inside the body on both the ontogenetic and phylogenetic level.

Anthroposemiotics now avoids biologism that occurs when human culture is reduced to communication systems traceable in other species, just as it avoids the anthropomorphic reduction of nonhuman animal communication to distinctive features and models specific to mankind.

Anthroposemiotics focuses on signs studied by specialists from different fields, viewing them at once in their specificity and interrelationship. These signs range from the signs of 'nature' to the signs of 'culture,' from verbal signs to nonverbal signs, from natural languages to artificial languages, from highly plurivocal and dialogical signs to univocal and monological signs, or better signals, signs endowed with varying degrees of indexicality, symbolicity, and

iconicity, signs of conscious and unconscious life. The anthroposemiosic universe includes the life of signs and the signs of life as they appear today in the biological and human sciences; signs of animal life and of specifically human life; human verbal signs and nonverbal signs; signs of adult life and signs of infants; signs of the human body both in its more culturally dependent and its natural-biological manifestations; signs of normal or pathological forms of dissolution and deterioration of communicative capabilities; signs that depend on natural languages and signs that, in contrast, have nothing to do with natural languages and, therefore, are refractory to the categories of linguistics; human intentional signs controlled by the will, and unintentional, unconscious signs in all forms of ideology, false consciousness, lying, deceit, and good faith.

Antigua and Barbuda: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of Antigua and Barbuda is English, with 67 000 speakers. Literacy is 89%. Significant minorities include North Levantine Spoken Arabic and Portuguese. The English spoken on Antigua and Barbuda is Leeward Caribbean Creole English, also spoken on Anguilla, St. Kitts, Montserrat, and Nevis.

The inhabitants of Barbuda have traditionally been small-scale farmers and fisherman with the result that sociolinguistic changes caused by slavery and the expansion of the sugar plantation system had relatively few direct effects on the island and the population of Barbuda remained more mixed for longer (*see* **Anguilla: Language Situation**).

In contrast, Antigua was a sugar island with the concomitant sociolinguistic effects exerted by slavery and the plantation system (*see* **Barbados: Language Situation**). The development of English on Antigua parallels that of Barbados. The production of sugar, being capital and labor intensive, required the establishment of large plantations, which forced small farmers off the land. Many emigrated to Jamaica. On Antigua, as on many sugar islands, the forced resettlement of slaves, stringent social control, short working life-spans – caused by poor conditions and epidemics – and the continuous influx of new slaves simultaneously stimulated the development of a stable Creole as well as preventing decreolization from occurring. Decreolization only began in earnest with emancipation in the 19th century and the spread of popular education.

Antonymy and Incompatibility

M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Incompatibility is the semantic relation in which two expressions have necessarily different reference. So, for example, *bottle* and *overture* are incompatible because nothing can be a bottle and an overture simultaneously. Often, *incompatibility* is used more particularly to mean incompatible items within a **semantic field**, such as *bottle/can/box*. In some traditions, the term ***contrast (set)*** is used for this relation. **Antonymy** involves special binary cases of incompatibility. These lexical-semantic relations are further defined below, and then main research issues are outlined. Slashes symbolize these relations – e.g., *cold/hot*.

Incompatibility and Contrast

Logical incompatibility (*bottle/overture* as well as *bottle/can/box*) is a semantic, rather than a lexical, relation. That is, the meanings are incompatible, rather than the words themselves, because the relation holds between specific senses of the word (so *bottle* 'container' and *bottle* 'courage' are incompatible with each other and with different items generally) and because formal properties of the words involved (such as pronunciation or register) are irrelevant to the relation. Logical incompatibility is rarely a focus of lexicological study, which usually concerns semantic paradigms, because no paradigm can be found in a group such as *argon/bottle/Democrat/overture*.

This logical sense of *incompatible* contrasts with another sense that is specifically used for incompatibility within a semantic field, as for *club/diamond/heart/spade*. We can further distinguish the logical-semantic *incompatibility* from a more pragmatic notion of *contrast*. *Incompatibility* definitionally includes no cases with referential overlap, but *contrast* can. For instance, if *green* and *blue* can both describe a particular shade of turquoise, then they are not incompatible, but do contrast, because they refer to categories with different, partly incompatible boundaries in the color field. In this sense, the opposite of *contrast* is *inclusion*: *blue/green* contrast, while *loden* and *lime* do not contrast with *green* but are included in its sense (*see* **Hyponymy and Hyperonymy**).

Antonymy and Opposition

The term *antonymy* is used in two ways. Some people (Lyons, 1977; Lehrer and Lehrer, 1982) use it specifically to refer to contrast between gradable predicates, so that *cold/hot* are antonyms, but *aunt/uncle* are not. Others (Jones, 2002; Murphy, 2003) use it to refer to any lexical pairs that constitute semantic **opposites**. In this general sense, *antonymy* can be defined as a relation in which two words share all relevant properties except for one that causes them to be incompatible. This is called **minimal difference**. For example, *aunt* and *uncle* share all semantic properties (parent's sibling[-in-law]) except sex, and *cold/hot* share all (extreme of temperature scale, neutral as to what it modifies) except which extreme is denoted. Antonymy contrasts with relations such as synonymy and hyponymy in its binarity and in that it is frequently argued to relate words as well as senses. For example, while *hot* and *freezing* are semantically incompatible, *freezing* is not the antonym of *hot* – only *cold* is.

Several logical antonym types have been identified. Antonym taxonomies vary in which types they include, but the three below occur in most taxonomies.

Gradable Contrariety (Classical Antonymy, Polar Opposition)

As noted, some theorists use *antonym* to refer only to contrasting gradable predicates such as *cold/hot*, *bad/good*, *big/little*. Such predicates are **gradable** in that they can hold to varying degrees (e.g., *hardly/very cold*, *hotter than*), and their relation is **contrary** in that the assertion of one entails the negation of the other (if something is hot, then it is not cold), but not *vice versa* (if something is not hot, it's not necessarily the case that it's cold – it could be tepid). Thus, there is some neutral semantic ground between the two antonyms. Gradable contraries are particularly interesting because they often exhibit **markedness** phenomena (Lehrer, 1985).

Complementarity (Contradiction)

Complementary (also called **contradictory**) antonyms are those whose senses completely bisect some domain (and thus are non-gradable). For example, every integer is either odd or even, so *even/odd* is a complementary pair. The assertion of one entails the negation of the other and *vice versa*: *X is odd* contradicts *X is even*, and *X is even* is synonymous with *X is not odd*. Complementarity is comparable to many cases of non-binary incompatibility that exhaust their referential domain (e.g., *animal/mineral/vegetable*). In this case, the entailment and contradiction relations are between the assertion or negation of one member of the set and the disjunction of the others. For instance, *X is an animal* contradicts *X is*

a vegetable or a mineral, and *X is not an animal* entails *X is a vegetable or a mineral.*

So-called **gradable complementaries**, such as *dishonest/honest*, lie between complementarity and contrariety. They seem to contradict each other (*X is not honest* entails *X is dishonest*, and *vice versa*), but a middle ground seems to exist, because we can assert that a person is *neither honest nor dishonest*. Even classic examples of complementarity, such as *dead/alive*, sometimes take on gradable qualities (e.g., *he's more dead than alive*). One solution to the problem of categorizing gradable complementaries is to treat the words involved as polysemous, having relative and absolute senses in contrary and complementary relations, respectively.

Directional Antonyms

Most taxonomies include at least one more type of antonym, which covers all or some of the following subtypes. **Converse** antonyms follow the pattern if X is *p* to Y, then Y is *q* to X. This covers examples such as *give* (*to*)/*receive* (*from*), *child/parent*, and *above/below*, in which each member describes the same relation or activity from a different perspective (e.g., using either X or Y as the landmark). For instance, *X gives Y to Z* entails *Z received Y from X*. **Reversive** opposites involve the undoing of some action: *tie/untie*, *build/demolish*. Both of these types are sometimes collected, along with other miscellaneous examples (e.g., *left/right*, *come/go*) in a general category of **directional** antonyms.

Other Types of Opposition

Many words that are considered to be opposites do not fit the above categories. For example, *learn/teach* seem to go together in a converse-like way, but they are not different perspectives on the same action, but rather two actions that typically co-occur. Gender opposites (*female/male, aunt/uncle*) are often considered to be complementary, but the existence of hermaphrodites calls that judgment into question. Other binary opposites are seemingly part of larger contrast sets, for example *happy/sad* (rather than *happy/angry* or *angry/sad*), raising the question of whether they are true contraries (on the same scale) or not (Ogden, 1967). Other pairs of words that go together, such as *gin/tonic* can be argued to be minimally different (they are similar in being part of the same drink, but different in being alcoholic/non-alcoholic), but many definitions of antonymy would not include such pairings. Still others, such as *Heaven/Hell*, contrast on so many levels (reward/punishment, ecstasy/agony, up/down, cool/hot) that they seem to flout the definition of antonyms as *minimally* different (Cruse, 1986; Murphy, 2003).

Research Issues

Interest in antonymy and incompatibility has shifted away from the logical properties of the relations and their subtypes and toward their roles in lexical organization and discourse. In part, this shift has been fueled by corpus methodology, which makes large-scale studies of antonym distribution possible.

Contrast and Lexical Development

Contrast relations are often seen as constraining lexical development, both at the individual (lexical acquisition) and the community (semantic change) levels. In the structural semantics tradition (Lyons, 1977; Coseriu and Geckeler, 1981; Cruse, 1986), meaning is often defined as at least partly dependent on the relations between words. The very existence of two words in the same lexical field forces their meanings to differentiate, and the existence of contrast relations between words makes it likely that they will referentially drift apart and their contrast relation will be extended to other senses for those words. For example, *black/white* are contrasted as color names, but also as racial terms that represent a complex of physical, genotypical, and cultural characteristics, and also mean 'evil/good' (*black/white magic*). These findings suggest that language users appreciate the relation as a relation between *words,* not just between senses, as discussed next.

A Lexical Relation?

As noted, incompatibility is a semantic relation among words' senses, but it can be argued that antonymy is a relation between words. In this case, we can use **opposite** to refer to the semantic relation of binary incompatibility (or contrast) and *antonym* to refer to the conventionalized pairing of two particular words with opposite meanings. The effects of such conventionalized pairing can be seen in several ways. First, some of the strongest associations in word association tests are anonymous stimulus-response pairs. If asked to respond with the first word that comes to mind, most people respond *white* to *black* and *sad* to *happy*, but have less consistent or non-antonymous responses for words without clear antonyms, such as *grey* or *joy*. Second, people use antonyms together in discourse at greater than chance rates and at greater rates than they use other possible semantic opposites. So, *weak* is more likely to be paired with *strong* in text than with another of its semantic opposites,

powerful (Charles and Miller, 1989). One might argue that such preferred pairings arise because they are semantically more perfect opposites, but a completely semantic explanation is not sufficient, because there is evidence that word form plays a role, too. For example, *homosexual* was established before *heterosexual,* but none of its semantic opposites gained status as an antonym for *homosexual* until a morphologically analogous term was invented (Murphy, 2003).

Acknowledging the conventionalization of antonym pairs raises several questions: How are such pairs established in the language, how are they acquired by individuals, and how are they mentally represented? Corpus studies have been a major tool in answering these questions and raising new ones. For example, Fellbaum (1995) has shown that the pairing of antonyms is not a strictly paradigmatic matter in which nouns have noun antonyms and verbs have verb antonyms, etc. So while the nouns *death* and *life* co-occur in sentences at higher than expected rates, so do the morphologically related pairs *deadly* (Adj) and *life* (N), *dead* (N) and *live* (V), and *die* (V) and *live* (Adj). Because antonyms co-occur and because their opposition is somewhat insensitive to part-of-speech, they defy traditional definitions of a 'paradigmatic' relation, leading some to claim that antonymy is a syntagmatic relation (while the semantic relation of opposition can still be classified as paradigmatic).

Discourse Functions and Constructions

Corpus studies of antonym co-occurrence also allow for the examination of how and where antonyms are used in discourse. The most comprehensive work on this to date has been Jones's (2002) description of discourse functions of antonyms, each of which is associated with particular morpho-syntactic frames, or constructions. The two major functions account for about 70% of antonym use. In **coordinated antonymy** (e.g., *X and Y*; *neither X nor Y*), the contrast between the antonyms is suspended in order to say something that is true of both X and Y. In sentence (1), the difference between *indoors/outdoors* is rendered irrelevant (for the use of the lights) in context.

(1) These lights can be used **indoors** or **outdoors**.

In the other major type of antonym, **ancillary antonymy**, one antonym pair creates or underscores a second opposition. For example, in sentence (2), the use of the conventionalized pair *long/short* heightens the contrast between *acquaintances* and *friends*.

(2) He was **long** on *acquaintances* but **short** on *friends*.

Jones' other seven types of antonyms may be more or less common in different genres of text and speech. Because the corpora searched contained formal writing, a remaining question is whether antonymy is used similarly in speech to create emphasis, cohesion, and interest.

Defining Antonymy

Finally, attention to antonymy as an arguably syntagmatic relation with particular discourse uses has brought into question earlier definitions that rely on logical notions such as incompatibility and entailment. The broader use of the term *antonym* to include all types of opposite relations raises questions regarding how the relation as a whole can be defined: What counts as opposition? Is antonymic opposition a semantic or pragmatic issue? How can we account for perceptions that some antonym pairs seem 'more antonymous' than others? Cruse (1994) has suggested that *antonym* is a prototype category, and that the prototypical antonym pair is diametrically opposed, symmetrical and binary, and exhausts the superordinate domain. This predicts that pairs such as *alive/dead* will be perceived as 'better antonyms' than examples such as *happy/sad* or *short/tall*, but that these others are still close enough to the prototype to count as antonyms in most contexts. Murphy (2003), on the other hand, has proposed that antonym relations are based on a pragmatic principle of contrast by minimal difference, and so, theoretically, almost any two words could count as opposites, if used in an appropriate context.

Apes: Gesture Communication

J Call and M Tomasello, Max Planck Institute for Evolutionary Anthropology, Liepzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

Apes use movements of the limbs, head, and body to communicate with conspecifics. The repertoire size varies between 20 and 30 gestures depending on the species (see papers in Call and Tomasello, 2004, for additional information). In addition to gestures, apes have a small repertoire of facial expressions and vocalizations (*see* **Nonhuman Primate Communication**). Apes use gestures in a variety of circumstances, including feeding, sexual, agonistic, grooming, travel, and play contexts. For instance, they extend their arm to beg for food, slap the ground to call attention to themselves, and put their arm around their mother's back to request to travel to a different location. These gestures fall within three basic sensory modalities: visual, auditory, and tactile. Visual gestures rely solely on visual information, auditory gestures rely mainly on sound production (although they also have an important visual component), and tactile gestures depend mainly on establishing physical contact with the recipient (see **Figure 1**).

Acquisition and Transmission

Unlike facial expressions and vocalizations, whose production seems tightly hardwired and not open to important modifications (see Snowdon, this volume), there is good evidence that apes can produce new gestures as needed. Although in general the gestural repertoires across groups of the same species overlap to a great extent, several studies have described a number of idiosyncratic gestures used by a single individual only (Goodall, 1986; Tomasello *et al.*, 1985). Tanner and Byrne (1993, 1996) also report much individual variability in the gestures used by gorillas. These idiosyncratic gestures are interesting because it is unlikely that they could have been either genetically determined or socially learned.

Chimpanzees (and probably other apes as well) learn their gestural signals via a process of ontogenetic ritualization (Tomasello, 1996). In ontogenetic ritualization two organisms essentially shape one another's behavior in repeated instances of a social interaction. This type of learning takes the following general form: (1) individual A performs behavior X; (2) individual B reacts consistently with behavior Y; (3) subsequently B anticipates A's performance of X, on the basis of its initial step, by performing Y; and (4) subsequently, A anticipates B's anticipation and produces the initial step in a ritualized form (waiting for a response) **in order to** elicit Y. The main point is that a behavior that was not at first a communicative signal becomes one by virtue of the anticipations of the interactants over time. There is no evidence that chimpanzees, or any other ape species, acquire gestural signals by means of imitative learning (Tomasello and Call, 1997). In fact, there is even a study reporting negative results (Tomasello *et al.*, 1997).

Flexibility

As noted previously, apes use multiple gestures in multiple contexts, but there is not a one-to-one correspondence between gestures and contexts. Thus, apes use a particular gesture in multiple contexts, and a particular context is served by multiple gestures. This dissociation between gestures and contexts is what allows subjects to change 'tactics' and try alternative

Apes use movements of the limbs, head, and body to communicate with conspecifics. The repertoire size varies between 20 and 30 gestures depending on the species (see papers in Call and Tomasello, 2004, for additional information). In addition to gestures, apes have a small repertoire of facial expressions and vocalizations (*see* **Nonhuman Primate Communication**). Apes use gestures in a variety of circumstances, including feeding, sexual, agonistic, grooming, travel, and play contexts. For instance, they extend their arm to beg for food, slap the ground to call attention to themselves, and put their arm around their mother's back to request to travel to a different location. These gestures fall within three basic sensory modalities: visual, auditory, and tactile. Visual gestures rely solely on visual information, auditory gestures rely mainly on sound production (although they also have an important visual component), and tactile gestures depend mainly on establishing physical contact with the recipient (see Figure 1).

Acquisition and Transmission

Unlike facial expressions and vocalizations, whose production seems tightly hardwired and not open to important modifications (see Snowdon, this volume), there is good evidence that apes can produce new gestures as needed. Although in general the gestural repertoires across groups of the same species overlap to a great extent, several studies have described a number of idiosyncratic gestures used by a single individual only (Goodall, 1986; Tomasello *et al.*, 1985). Tanner and Byrne (1993, 1996) also report much individual variability in the gestures used by gorillas. These idiosyncratic gestures are interesting because it is unlikely that they could have been either genetically determined or socially learned.

Chimpanzees (and probably other apes as well) learn their gestural signals via a process of ontogenetic ritualization (Tomasello, 1996). In ontogenetic ritualization two organisms essentially shape one another's behavior in repeated instances of a social interaction. This type of learning takes the following general form: (1) individual A performs behavior X; (2) individual B reacts consistently with behavior Y; (3) subsequently B anticipates A's performance of X, on the basis of its initial step, by performing Y; and (4) subsequently, A anticipates B's anticipation and produces the initial step in a ritualized form (waiting for a response) **in order to** elicit Y. The main point is that a behavior that was not at first a communicative signal becomes one by virtue of the anticipations of the interactants over time. There is no evidence that chimpanzees, or any other ape species, acquire gestural signals by means of imitative learning (Tomasello and Call, 1997). In fact, there is even a study reporting negative results (Tomasello *et al.*, 1997).

Flexibility

As noted previously, apes use multiple gestures in multiple contexts, but there is not a one-to-one correspondence between gestures and contexts. Thus, apes use a particular gesture in multiple contexts, and a particular context is served by multiple gestures. This dissociation between gestures and contexts is what allows subjects to change 'tactics' and try alternative

Figure 1 Three gestures corresponding to three sensory modalities: (A) visual: hand-begging, (B) auditory: hand-clapping, and (C) tactile: arm-on.

gestures when those that they already have used are ineffective. On the one hand, this ability to try different gestures toward the same goal is analogous to their ability to produce multiple solutions to achieve a certain goal. For instance, presented with a problem in which an out-of-reach food reward is hanging from the ceiling, apes can, among other things, climb a box to reach the reward, throw objects at the reward, or hit the reward with a stick to knock it down. On the other hand, the use of gestures is quite different from the use of vocalizations, in which there is usually a one-to-one correspondence between signals and contexts (indeed, a one-to-one correspondence is probably a necessary condition for those signals to be effective). For instance, alarm calls are specific to the detection of predators, and recruitment calls are specific to enlisting help from allies in agonistic contexts.

Apes also can use combinations of gestures – be they repetitions of the same gesture or combinations of different gestures. In chimpanzees, approximately 30% of the gestures appear in combinations. There is no evidence, however, that these combinations acquire a different meaning from that of their constituent gestures or that they modify the meaning of single gestures. In other words, there is no evidence of syntactic rules in gestural communication. It is more likely that these combinations are used to emphasize the message or as a way to try a different approach to a problem when a single gesture is not producing its desired outcome.

Audience Effects

Several observational studies have shown that individuals of all ape species adjust their gestures to the attentional state of the recipient. This means that apes use gestures from each sensory modality (i.e., visual, auditory, and tactile) differentially depending on the spatial orientation of the recipient. In particular, individuals use visual gestures preferentially when the recipient is facing them. In contrast, they do not show such a specificity for auditory, and especially for tactile, gestures (Call and Tomasello, 2004). For instance, chimpanzee juveniles give only a visual signal to solicit play (e.g., 'arm-raise') when the recipient is already oriented appropriately, but they use their most insistent attention-getter, a physical 'poke-at,' most often when the recipient is socially engaged with others.

Several experimental studies have confirmed and extended this result by showing that apes are specially attuned to the face orientation of the recipients, not just their presence/absence or their overall body orientation. Apes will beg food from a human who is oriented toward and looking at them rather than from one who is oriented toward them but with the face turned away (Kaminski *et al.*, 2004). Furthermore, when competing for food, chimpanzees avoid taking food from the side toward which the human has the face, but not the body, turned (Hare *et al.*, submitted). Moreover, chimpanzees and bonobos show special sensitivity, compared with gorillas and orangutans, to the attentional state of recipients. When begging food from a human who has turned the back and face away from them, they move around to face the human and then gesture, even if doing so entails abandoning the location of the potential food source (Liebal *et al.*, in press). Chimpanzees can also produce sounds or will touch a human who is not paying attention in order to request food (Gómez, 1996; Hostetter *et al.*, 2001).

As noted previously, chimpanzees have a rich natural repertoire of gestural signals and can also acquire novel gestures. Some of the most compelling cases that demonstrate the ability to acquire novel gestures involve the acquisition of human gestures. Two prominent examples are pointing and sign language.

Pointing

Using an extended index finger (or the whole hand) is not a gesture that apes use to direct the attention of

their conspecifics. Some authors argue that the lack of pointing with an extended arm and finger is actually not surprising at all because chimpanzees point with their body orientation (Menzel, 1974). In other words, chimpanzees do not display pointing (with an extended arm) because they already have other ways to point. Moreover, de Waal and van Hooff (1981) observed that during recruitment episodes following an aggressive incident, chimpanzees use 'side-directed' behavior to indicate enemies to their potential allies. They do this by using an extended arm toward the aggressors. Although this behavior could be construed as pointing at the enemies to inform potential allies, it is also true that chimpanzees use an extended arm toward their potential allies. Therefore, it is not clear whether pointing with the body or side-directed behavior constitutes genuine cases of intentionally directing attention as opposed to behaviors that the other can read but that the sender does not intend to send as referential acts.

Despite the lack of pointing gestures among apes, it is clear that they can spontaneously develop this gesture when they interact with humans. There are numerous examples of language-trained apes' acquiring this gesture in the company of humans (Savage-Rumbaugh *et al.*, 1986; Krause and Fouts, 1997; Miles, 1990; Patterson, 1978). Most apes acquire the whole-hand point, but a minority of individuals use the index-finger point. For instance, Krause and Fouts (1997) systematically studied the pointing of two language-trained chimpanzees and found that they were capable of pointing very accurately to various targets. In this study humans could reliably locate the position of rewards on the basis of the information provided by the chimpanzee gestures. In contrast, pointing behavior has not been documented either in the wild or in groups of captive chimpanzees interacting with other chimpanzees. Recently, Leavens and Hopkins (1998; see also Leavens *et al.*, 1996) have shown that even non-language-trained chimpanzees can develop pointing gestures to direct the attention of humans. These authors found that 40% of the chimpanzees they studied pointed with the whole hand (with 5% using an index finger extension) to indicate the location of food to humans. These pointing gestures were accompanied with gaze alternation between the human and the food, and the chimpanzees persisted in using this gesture until they received the food. These features suggest that pointing gestures were both intentional and referential. These gestures were observed only when chimpanzees interacted with humans, not with other chimpanzees. Since captive chimpanzees (both mother- and human-reared) interact with humans extensively, and humans are especially attuned to the pointing gesture, it is not surprising that chimpanzees can quickly capitalize on this and develop pointing gestures. So the current evidence indicates that chimpanzees, regardless of their rearing history, can develop the pointing gesture to direct the attention of humans to locations or objects that they desire.

Sign Language

Apes can be trained to use some aspects of human sign language (e.g., Fouts, 1975; Gardner *et al.*, 1989; Miles, 1990; Patterson, 1978). Most studies have used American Sign Language or some version of it. Apes can acquire nouns, verbs, adverbs, pronouns, and adjectives. In some cases, these signs are iconic (i.e., their topography is reminiscent of the referent they represent), but in other cases they are truly symbolic. By using these signs, apes are capable of displaced reference, that is, they can refer to things that are not currently perceptually available. Some theorists have proposed that the use of symbolic systems allows apes to solve certain problems such as analogies in a qualitatively different way from non-language-trained apes (Premack, 1983). However, non-language-trained apes can also solve these problems if certain slight modifications are implemented. Moreover, it is often hard to know whether this putative superiority of language-trained apes is a result of language *per se* or the rearing environment (so-called enculturation) that the apes in these projects experience (Call and Tomasello, 1996; Tomasello and Call, 2004). Signing apes can combine multiple signs to request things like food or play, to answer queries, or to ask questions. These combinations do not appear to follow syntactic rules. Most studies have reported a repertoire size of about 200 words or more. Apes use signs to communicate with humans and also among each other. There are even some reports of apes' learning signs from other apes without human intervention (Fouts, 1975). They even use signs toward themselves when they are reading magazines on their own.

Summary

Apes have a gestural repertoire of 20 to 30 gestures, which they use mainly in social contexts such as play, grooming, and nursing, and during sexual and agonistic encounters. Apes can produce novel gestures, including some typical human gestures such as pointing, or even learn the rudiments of sign language. Although the gestural repertoires across groups of the same species overlap to a great extent,

some individuals display idiosyncratic gestures. It is hypothesized that ontogenetic ritualization, not imitative learning, is one of the main mechanisms of acquisition of gestures in apes. Apes use a single gesture in multiple contexts, and a single context is served by multiple gestures. These gestures can be used alone or in combinations of the same or different gestures. Apes adjust their gestures to the attentional state of the recipient. This means that they use visual gestures preferentially when the recipient's face is visible to them. This flexibility in acquisition and use suggests that gestural communication has played an important role in the evolution of language.

Aphasia Syndromes

N Pratt, University of Louisville, Louisville, KY, USA
H A Whitaker, Northern Michigan University, Marquette, MI, USA

Throughout recorded history, there has been documentation of the loss of speech due to brain injury. Research in the 19th century demonstrated that language impairment was likely to occur with injury to the peri-Sylvian region of the left cerebral hemisphere. Goodglass and Kaplan (1983: 5) defined aphasia as "...the disturbance of any or all of the skills, associations and habits of spoken or written language produced by injury to certain brain areas that are specialized for these functions."

Research on language impairments, studying many numbers of patients and considering reoccurring locations of injury to the brain, has demonstrated that language functions are relatively localized and typically lateralized. The left hemisphere's involvement in language focuses on the formation and production of words, whereas the right hemisphere's involvement is related more to aspects of discourse (Caplan, 2000). The core language system is primarily situated in the left hemisphere and comprises four 'centers,' which can be associated and distinguished by relatively identifiable impairments. These include the superior–posterior temporal lobe, usually referred to as Wernicke's area, the supramarginal gyrus and its surrounding cortex, the angular gyrus and its surrounding cortex, and the inferior–posterior frontal lobe, usually referred to as Broca's area.

In an earlier approach to aphasia syndromes, language disorders were divided into two categories based on speech output (Goodglass and Kaplan, 1983), the fluent and nonfluent aphasias. Fluent aphasias are typically caused by lesions posterior to the rolandic fissure, often leaving Broca's area intact; the typical qualities of fluent aphasia include an ease of articulation, long fluent runs of words formed with a variety of grammatical constructions accompanied by a difficulty in finding the proper words for substantives and imaginable action words (Goodglass and Kaplan, 1983). Nonfluent aphasia is marked by difficulties with articulation, with the initiation of speech, and with the production of well-formed grammatical sequences (Goodglass and Kaplan, 1983). Nonfluent aphasia typically occurs with anterior lesions, usually in Broca's area, or larger lesions involving the supra-Sylvian cortex.

There are other descriptive systems for classifying aphasia syndromes, some based more on linguistic characteristics and others based more on clinical features. In general, the classical aphasia syndromes discussed in this article are widely applied in clinical as well as research settings, even though they are insufficiently detailed to encompass every single observable form of language disorder. Although linguistically highly selective language disorders are uncommon, they can still be found; such patients are not easily classified in the core aphasia categories.

Although everyone today would agree that aphasia is a language impairment that is due to brain injury, there are well-known controversies in the descriptions of aphasia because of debate over the definition of language (Benson and Ardila, 1996) and what linguistic system, if any, should be used to describe language disorders. Some interpret aphasic impairment for the purpose of analyzing linguistic structures, others examine aphasic language as a cognitive function, and still others work at a neurophysiological or neuroanatomical level (Benson and Ardila, 1996). Debate also arises as to whether the descriptions of aphasia support syndromes based purely on anatomical criteria or purely on linguistic or psychological theories (Goodglass, 1993). Correlating these different approaches to aphasia with tasks of verbal output, verbal interpretation, neuoroanatomical correlates, and behavioral dimensions can be daunting. However, there are a few agreed-upon core aphasia syndromes that incorporate a reasonable proportion of aphasia symptomatology and suffice to describe the majority of patients with aphasia; in addition, it seems to be the case that a significant proportion of aphasia research still employs these core aphasia syndromes as descriptors of research subjects. The syndromes discussed next were originally outlined

However, there are a few agreed-upon core aphasia syndromes that incorporate a reasonable proportion of aphasia symptomatology and suffice to describe the majority of patients with aphasia; in addition, it seems to be the case that a significant proportion of aphasia research still employs these core aphasia syndromes as descriptors of research subjects. The syndromes discussed next were originally outlined

as part of the Boston Diagnostic Examination for Aphasia (BDEA) (Goodglass and Kaplan, 1983).

Broca's Aphasia

Broca's aphasia, also referred to in some syndrome classifications as verbal aphasia, expressive aphasia, efferent motor aphasia, or motor aphasia, typically results from a lesion to the left posterior and lower frontal lobe and the subjacent white matter, often extending back through the lower precentral and postcentral gyri, and possibly including the inferior anterior parietal lobe, a rather wider geographical region than the region known as Broca's area, generally Areas 44 and 45 of the left hemisphere. Paraphrasing from Goodglass (1993: 210), a continuing Broca's aphasia would typically involve a lesion encompassing Broca's area (pars opercularis and pars triangularis) in the left frontal lobe cortex, usually extending posteriorly to include the lower portion of the motor strip. A lesion causing Broca's aphasia typically extends downward to the periventricular white matter, because a purely cortical or shallow lesion produces only a transient disorder.

Broca's aphasia is a common variant of the category nonfluent aphasia. Patients with Broca's aphasia tend to produce poorly articulated words and commonly transpose phonemes, and there is usually difficulty in initiating speech. Vocabulary is often limited and grammatical output tends to be confined to basic and overlearned speech elements. The production of speech tends to be in short phrases with a fewer number of words than expected, with many pauses. Overall linguistic ability seems to rely on the familiarity of the message that is spoken (Goodglass, 1993). It is common to observe agrammatism in patients with Broca's aphasia; agrammatism is a term used to describe speech output in which elements of grammatical structure are omitted, typically the so-called function words or grammatical functors (Benson and Ardila, 1996). Anomia is also fairly common; anomia causes patients to struggle with finding the appropriate word, both in conversational speech and in confrontational naming (e.g., what is this?). Many patients with Broca's aphasia have difficulty comprehending both relational words and varying syntactic structures (Benson and Ardila, 1996), although most demonstrate the ability to comprehend single nouns, verbs, or adjectives (Goodglass, 1993). Errors may occur in the ordering of words, although strictly speaking, word order errors would be called paragrammatism. Nouns appear to be preserved best in Broca's aphasia, whereas grammatical functors are the most impaired (Benson and Ardila, 1996). Usually there are also prosodic changes, including changes in inflection, pitch, and rhythm, that may distort speech output; this is commonly referred to as dysprosody (Benson and Ardila, 1996). Repetition often shows the same impairments as in conversational speech.

The writing ability of patients with Broca's aphasia tends to be affected in a manner analogous to speech output, but reading ability may be only mildly impaired (Benson and Ardila, 1996; Goodglass and Kaplan, 1983). Certain lesions giving rise to Broca's aphasia can also affect 'nonspeech oral movements' (Goodglass and Kaplan, 1983). A large majority of parients will show weakness of right-sided motor movements (Benson and Ardila, 1996). Writing ability tends to be affected with misspellings, letter omissions, and poor formation of letters occurring (Benson and Ardila, 1996).

People affected with Broca's aphasia are generally aware of their language impairment and will often struggle to produce the correct response. Once such patients begin to recover, they are often able to name objects at a functional level, whereas the syntactic structure of speech production is still limited. Current research shows that the lesions typically leading to Broca's aphasia most often affect both the inferior frontal lobe and the anterior inferior portion of the parietal lobe; thus, research suggests that both these areas are the probable sites for the production of language output and thus are an essential component of the so-called language core.

Wernicke's Aphasia

The most common fluent aphasia is Wernicke's aphasia, which has also been referred to as syntactic aphasia, acoustic aphasia, sensory aphasia, or receptive aphasia. The responsible lesion is predominantly found in the posterior portion of the first temporal gyrus of the left hemisphere and frequently includes the middle temporal gyrus; such lesions often continue back to the occipital lobe and inferior parietal–temporal lobe in the vicinity of the supramarginal and angular gyri. From Goodglass (1993: 211), we learn that "lesions that extend posteriorly to include the region of the angular gyrus are likely to produce severe reading and writing disorders in addition to the effects on speech comprehension. When damage to this temporal region occurs, patients are typically inflicted with an impaired ability to comprehend auditory stimuli. Their own speech often appears to be fluent but is typically produced in a paraphasic manner."

As in Broca's aphasia, syntax is often affected, but in Wernicke's aphasia, function words, rather than being omitted, are often used improperly or added extraneously; grammatical word order constraints may

be violated as well. This sort of syntactic impairment is called 'paragrammatism.' Sentence production in Wernicke's aphasia is often devoid of complex verb tenses and embedded subordinate clauses, exemplifying a simple declarative word order (Goodglass and Kaplan (1983: 80). Although not common in all patients with Wernicke's aphasia, many such patients show an excessive output even to the point of adding additional syllables, words, or phrases to sentences; in addition, jargon aphasia is more characteristic of the early stages of Wernicke's aphasia (Benson and Ardila, 1996). Most classification schemas consider jargon aphasia a subtype of Wernicke's aphasia, with verbal output substitutions that are literal (at the phonemic level), verbal (at the word level but recognizable), or neologistic (also at the word level but unrecognizable) (Benson and Ardila, 1996).

The writing ability of patients with Wernicke's aphasia is often motorically intact, but will normally reflect the patient's fluent paraphasic speech, demonstrating a frequently disorganized and rambling style, with occasional-to-frequent repetitions of words or phrases and a dearth of substantives and concrete action words. Reading tends to be impaired as well, although the greater deficit is in auditory comprehension. Patients with Wernicke's aphasia typically exhibit a 'press of speech' and, concomitantly, appear to be unaware of their deficits. As noted above, comprehension, particularly in the auditory modality, shows a severe deficit, regardless of whether the words are high frequency or the objects are common (Goodglass, 1993).

Conduction Aphasia

Wernicke's and Broca's aphasias affect the posterior or anterior portion of the rolandic fissure, respectively; on the other hand, by some accounts, it is the cortices supplied by the upper and lower divisions of the middle cerebral artery that are affected. There is greater agreement that the lesions causing conduction aphasia tend to be located predominantly in the vicinity of the arcuate fasciculus, the pathway connecting the temporal lobe to the frontal lobe. There are also reports that lesions causing conduction aphasia may be located in the superior temporal gyrus or within the insula. As reported in Goodglass (1993), "a large proportion of Conduction aphasics have a lesion in the supramarginal gyrus"; however, lesions elsewhere along the border of the Sylvian fissure, extending to the white matter below, may be seen. The size of the lesion in conduction aphasia is usually smaller than in either Broca's or Wernicke's aphasia; as noted above, a patient with an extensive lesion of the posterior Sylvian zone will typically exhibit the features of Wernicke's rather than conduction aphasia. Because the lesions are more centrally located, conduction aphasia has also been termed central aphasia, repetition aphasia, or afferent motor aphasia. Although the speech output may be similar to that in Broca's aphasia, the paraphasic output symptomatology is characteristically similar to that in Wernicke's aphasia. The difference is that patients with conduction aphasia are able to comprehend language and produce a relatively fluent speech output, with their most notable impairment being difficulty with repetition (Goodglass and Kaplan, 1983). In addition to the repetition deficit, patients with conduction aphasia are often afflicted with anomia; "literal paraphasias (phonemic substitutions) may contaminate both spontaneous verbal output and attempts to repeat spoken language" (Benson and Ardila, 1996: 130).

Conduction aphasia is usually characterized by fluent, literal conversational speech and typically decent comprehension skills (Benson and Ardila, 1996), and, as noted above, the most distinctive characteristic is the abnormality found in repetition (Benson and Ardila, 1996). Within short phrases, articulatory fluency is usually quite good but patients with conduction aphasia may show a form of phonemic paraphasia (Goodglass, 1993). Although within-phrase syntactic patterns are normal, most patients show some difficulty with sentences containing pronouns and grammatical functors as well as polysyllabic words. Other characteristics that may be found include difficulties in writing, showing some forms of agraphia and ideomotor apraxia (Benson and Ardila, 1996). Writing ability is often parallel to the poor speech output, showing deficits in spelling and letter omissions or substitutions. Patients with conduction aphasia are generally aware of their speech and language deficits.

Anomia

Anomia is a form of aphasia that has also been called amnesic or amnestic aphasia, nominal aphasia, or semantic aphasia. Anomia is also an impairment that may be found in any variety of aphasia and for that reason, no specific localization for the causative lesion has been or is likely to be documented. Several aspects of anomia share features with Wernicke's aphasia; one main difference is in the absence of literal (phonemic) paraphasias and, since anomia is described by the failure to name or to retrieve names and/or nouns, auditory comprehension is unaffected, unlike in Wernicke's aphasics.

Many anomic patients are fully competent in speech, but lack the substantive words related to concepts. As a result, their speech is often described as 'empty.' Speech rate, articulation, and syntactic

form are generally normal with the exception of the pauses that signal deficits in word finding, especially nouns or words of informational content (Goodglass, 1993). Object recognition is usually good; however, many anomic aphasics are unable to comprehend nouns or verbs in isolation. In general, reading and writing are preserved, except for severe cases in which an anomic alexia or anomic agraphia is also involved; in such cases, then, reading and writing skills will appear similar to speech output. Anomia is often the first language disturbance to be manifested from brain tumors (Goodglass and Kaplan, 1983) and it may be an early sign of a developing language disorder in adults.

Alexia with Agraphia

Both the location and the size of the lesion will strongly influence the manifestation of any aphasia, but these are particularly relevant in the impairment described as alexia with agraphia (Arbib *et al.*, 1982). Alexia with agraphia is also known as parietal–temporal alexia, central alexia, semantic alexia, or angular alexia (Benson and Ardila, 1996) and may overlap the syndrome known as letter blindness. The causative lesions are predominantly found in the region of the angular gyrus. Patients suffering from alexia with agraphia display impairments in both reading and writing skills. In general, their ability to copy words tends to be better preserved than their spontaneous writing ability (Benson and Ardila, 1996). The inability to read and write extends into domains other than visual language: numbers, musical notation, and chemical formulas can also be impaired (Benson and Ardila, 1996). Speech output and auditory comprehension may be somewhat impaired but typically only in a mild form of anomia.

The Transcortical Aphasias

In many of the classic descriptions of language–brain relationships, there was the notion of the language core, the temporo-parieto-frontal cortex of the language-dominant hemisphere, in which resides the ability to repeat what is heard. The term 'transcortical' originally explained the ability to reproduce the phonological representation of a word without being able to construct its meaning (Benson and Ardila, 1996), analogous to the ability to repeat a word in a foreign language that one does not understand. The various forms of transcortical aphasias are, of course, not literally 'transcortical.' The putative causative lesions are extra-Sylvian in location, that is, outside the classic language core, which is the predominant anatomically distinguishing feature of these aphasias (Benson and Ardila, 1996; Gonzales-Rothi, 1997). The following briefly describes the generally accepted classical forms of transcortical aphasias.

Transcortical Sensory Aphasia

This is a relatively rare form of aphasia that occurs when a lesion functionally isolates Broca's and Wernicke's areas from the rest of the brain, leaving these two areas sufficiently unimpaired such that repetition is preserved but neither comprehension nor spontaneous speech is intact. Goodglass (1993) suggested that transcortical sensory aphasia is commonly produced by deep lesions, inferior to the angular gyrus, between the posterior end of the fissure of Sylvius and the temporal–occipital junction. Such a lesion allows information to project only from Wernicke's area into Broca's region, causing an "isolation which inhibits knowledge and perception to interact with the rest of the brain" (Goodglass and Kaplan, 1983). Another way of describing transcortical sensory aphasia is to consider it a form of Wernicke's aphasia, i.e., a severe comprehension deficit, in which repetition, and thus articulation, is well preserved. Despite intact articulation, repetition speech may be paraphasic, neologistic, anomic, and even echolalic (Goodglass and Kaplan, 1983; Benson and Ardila, 1996). Typical output may appear to be 'uninhibited' (Benson and Ardila, 1996). Patients tend to be unaware of their impairment (Goodglass, 1993) and their speech can occasionally be misinterpreted as a psychogenic problem, such as schizophrenia (Benson and Ardila, 1996). Writing ability is usually disturbed as well and is similar to the writing style seen in patients with Wernicke's aphasia (Benson and Ardila, 1996).

Transcortical Motor Aphasia

Another form of the transcortical aphasias is transcortical motor aphasia, sometimes known as dynamic aphasia or anterior isolation syndrome. The causative lesions are typically found on the mesial face of the anterior left frontal lobe, in the region of the supplementary motor cortex, or along the lateral aspect of the left frontal lobe, thus outside of what is traditionally thought of as Broca's area. Goodglass (1993) pointed out that lesions causing transcortical motor aphasia are usually smaller than those associated with Broca's or Wernicke's aphasia. Presumably they impinge on an anterior subcortical site that may form part of a circuit linking the motor speech area with the supplementary motor area and certain limbic structures considered essential for the initiation of speech. It has not been established whether cortical

involvement of the lateral surface, as in Broca's area, affects the symptom picture (Goodglass, 1993: 213). Functionally, the causative lesion separates the processing of speech from the mechanisms for initiating the action to talk. Patients with transcortical motor aphasia tend to be mute and may have an associated general akinesia (Benson and Ardila, 1996).

Although transcortical motor aphasia is an impaired ability to initiate speech, once such a patient begins talking, speech output is typically relatively intact. Comprehension can be fairly normal and so can repetition. Prosody, articulation, and grammar remain well preserved even when verbal output is delayed and/or interrupted by false starts, incomplete sentences, or verbal paraphasias (Benson and Ardila, 1996). When asked to say something, or otherwise initiate a response without cues, these patients have difficulty responding. However, when asked to repeat words, phrases, or sentences, performance is characteristically flawless (Goodglass, 1993). Regarding word retrieval, there is a range in ability, with some patients, for example, being able to perform well on tasks such as object naming. Verbal output may improve if related to common, repetitious material (Goodglass, 1993).

Mixed Transcortical Aphasia

Often associated with Pick's disease or carbon monoxide poisoning, mixed transcortical aphasia, also known as the isolation syndrome, appears to functionally isolate the peri-Sylvian speech areas, the so-called language core. The primary remaining language ability is a striking ability to repeat words, phrases, and sometimes whole sentences, the opposite of the conduction aphasic patient. Although articulatory fluency is generally well preserved, the quasiautomatic repetition, often a frank echolalia, is prominent in the context of few other intact language functions. There is typically a complete alexia and agraphia, with an occasional ability to scribble meaninglessly. As pointed out by Benson and Ardila (1996), other than the ability to repeat, patients with mixed transcortical aphasia exhibit the characteristics common to global aphasia.

Auditory Agnosia

In auditory agnosia, otherwise known as pure word deafness, patients are unable to recognize speech sounds, but are able to hear other nonlanguage sounds. Nonlanguage sounds, such as environmental noises, animal sounds, or music, can be relatively well distinguished and recognized. Other language abilities – speech production, reading and writing – generally remain intact. In most cases, Wernicke's area is undamaged, but the lesion destroys Heschl's gyrus (primary auditory cortex) in the language hemisphere and destroys or compromises the afferent auditory pathways from the opposite hemisphere. The result is that Wernicke's area is functionally isolated from auditory input; the patient can hear but cannot understand or repeat speech sounds. These patients do not reflect any of the symptoms common to Wernicke's aphasia except for the impaired ability to recognize speech sounds or repeat them.

Agraphia

Agraphia is the loss of the ability to produce written language, caused by specific brain lesions. There are three main forms of agraphic disorders. The first is phonological agraphia, which is an impairment in writing pronounceable pseudo-words to dictation, with a much better preserved ability to write real words and occasional difficulties with grammatical functors and abstract words (Kaplan *et al.,* 1998: 315). A second form is semantic agraphia, which can occur with focal lesions but is more commonly found in the early stages of senile dementia of the Alzheimer's type; such patients may write real words and pseudo-words normally to dictation, but they make frequent semantic errors in written confrontation naming or written descriptions (Kaplan *et al.,* 1998: 315–316). A third form is lexical agraphia; these patients preserve the phonological form of the word when writing, but produce spelling errors that normalize spelling to approximate to how the word sounds (Kaplan *et al.*, 1998). Because written language so often mirrors spoken language, agraphia is typically associated with a specific variety of aphasia (Benson and Ardila, 1996). But, because writing also includes visuospatial skills, as well as motor skills that differ from speech, impairments in spatial orientation or visual discrimination can cause agraphia without aphasia (Benson and Ardila, 1996). Patients with pure agraphia frequently have damage within the frontal lobe, but a few cases have also shown damage within the left superior parietal lobe (Benson and Ardila, 1996).

Alexia (Dyslexia)

In the literature, some authors reserve dyslexia for developmental reading problems and alexia for adult acquired reading problems; here we simply use the terms as in the source literature: as above, the focus is on adult impairments caused by brain damage. Without signs of a writing disorder, alexia is diagnosed as a disturbance in the ability to recognize words and/or

letters (Kaplan *et al*., 1998). We recognize several varieties of alexia including literal alexia (also referred to as letter blindness), verbal alexia (or word blindness), general alexia (reading impairments that may be of a grammatical or semantic nature or something else), and hemialexia (the ability to attend to only half of a word or line) (cf. Benson and Ardila, 1996, or Goodglass and Kaplan, 1983, for more clinical descriptions). In forms of pure alexia, patients are able to visually see written language stimuli, but are unable to recognize them as letters, words, or both. In these cases, the lesion tends to destroy the visual association cortex in the language hemisphere together with the callosal afferent fibers projecting from the other hemisphere, effectively isolating the language core from visual input. A variant of pure alexia is known as 'letter-by-letter' reading, as patients seem to process one letter at a time, read aloud, before identifying a word (Kaplan *et al*., 1998). For many pure alexic patients, words may be successfully comprehended if they are spelled out loud or traced on the palm, thus bypassing visual input to access the language core (Kaplan *et al*., 1998).

Three dyslexias (or alexias) have been defined in terms of the putative locus in a psycholinguistic model of reading: deep dyslexia, surface dyslexia, and phonological dyslexia (Coltheart *et al.,* 1980; Coltheart, 1996; Patterson *et al.,* 1985). These are defined as follows:

Patients with deep dyslexia usually have sustained a lesion sufficiently large to produce an aphasia, commonly a Broca's aphasia; their reading is characterized by semantic errors in reading aloud (the error is semantically related to the target word) and may also show visual errors (the error is visually similar but otherwise unrelated to the target word), morphological errors (the error is a morphological variant of the target word), a concreteness effect (concrete words are easier to read than abstract ones), a difficulty in reading grammatical functors, and a pronounced inability to read nonword letter strings that could be possible words in the native language (e.g., for English, the string *vib* or *phite*).

Patients with surface dyslexia have a reading impairment characterized by their **ability** to read orthographically regular words (approximately 75% of the English lexicon is orthographically regular, e.g., words such as *top, jelly,* and *sing*) but a pronounced difficulty reading orthographically irregular words (in English, words such as *pint, come,* and *bury* are orthographically irregular). Errors made by surface dyslexic patients on irregular words tend to be regularizing errors; that is, patients pronounce them as though they were orthographically regular. Surface dyslexic patients are able to read pronounceable nonwords, e.g., HEAF would be read to rhyme with the word *leaf*, which is regular, but not *deaf,* which is irregular.

Phonological dyslexic patients can read real words but have difficulty reading pronounceable nonwords, as is the case with deep dyslexic patients; however, patients with phonological dyslexia do not make the semantic errors that deep dyslexic patients do. Otherwise, the boundary between deep and phonological dyslexia is not always sharp and some patients seem to have characteristics of both types.

In conclusion, the main recommendations for continued use of the aphasia syndromes discussed above are convenience and consistency. A great deal of modern research in neurolinguistics, clinical neuropsychology, and the cognitive neurosciences employs the classical aphasia syndromes for identifying patient groups, notwithstanding the research in the late 20th century that casts doubt on the validity of the location of causative lesions, other research that questions the logical coherence of the symptomatology of syndromes, and still other research that questions the possibility of studying groups of patients classified in terms of these syndromes. The most widely used test battery in the United States, the BDAE (Goodglass and Kaplan, 1983), from which the major aphasia syndrome typology originates, claims to be able to classify only approximately three-fourths of all patients with language impairments. One may still argue, and many contemporary publications will attest, that the patients who can be so classified into syndromes can, sensibly and statistically, be grouped under these headings for research purposes. *Caveat emptor.*

Apollonius Dyscolus and Herodian

D L Blank, University of California, Los Angeles, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Lives

We know little about the lives of the great grammarians Apollonius Dyscolus and Herodian. Herodian is said to have moved from Alexandria to Rome, where he enjoyed the patronage of Emperor Marcus Aurelius (161–180 A.D.), to whom his *General Prosody* is dedicated. Apollonius was Herodian's father and is therefore thought to have been active in the reign of Antoninus Pius (138–161 A.D.). Apollonius lived all his life in Alexandria, where he appears to have taught and to have had a role in grammatical debates and competitions. The ancient *Life* of Apollonius explains his cognomen ('Grouchy') by appeal to his crabbed style, his ill temper, or the difficulty of the problems he posed in competition. It also states that Apollonius was so poor that he had to write on potsherds and that he educated his son Herodian so well that he broke with his father (or else that a break occurred because Herodian disliked his stepmother), but this is presumably a supposition from Herodian's many grammatical disagreements with his father.

Works

Apollonius is the only Greek grammarian before late antiquity some of whose works survive in their original form. Three of Apollonius' extant treatises are on individual parts of speech: *Pronouns, Adverbs,* and *Conjunctions*. Each of these falls into broad sections on the 'sense' and 'form of the vocal sound' of the part of speech in question. Under the first are discussed the name and definition of the part of speech, its kinds, and questions about the assignment of certain words to it: all these questions are decided on the basis of the sense. The second part discusses the forms and prosody of individual words in the class, including dialect and 'corrupt' forms, for none of these changes affects the sense. The most important, and latest, of Apollonius' surviving works is his *Syntax*, the four books of which survive almost in their entirety. This work studies the way in which each of the parts of speech may be combined with the noun and verb—"the most vital parts"—to form a complete sentence. Many of Apollonius' other works survive only in fragments. Among these are highly influential treatises on *Names* and *Verbs*, books on *Orthography* and *Dialects*, as well as the philological subject of false stories in literature, and a series of works that, together with the others, seems to build a study of language from the ground up: *Elements* (i.e., letters and letter sounds), *Prosodic Markings, Forms, Division of the Parts of Speech, Voice*.

Herodian's works survive only in excerpts and epitomes, although in one papyrus (Wouters, 1979: 223–224) and two palimpsests (Hunger, 1967; Reitzenstein, 1897: 302; Alpers, 1969: 13 ff.), we obtain a glimpse of something closer to his original arrangement. The only exception is the extant brief work *Uniquely Declined Words*. Herodian is most closely associated with studies of the prosody of individual words, beginning with books called *Iliadic*, *Odyssean*, and *Attic Prosody*, and leading to his great *General Prosody*. These works treated the proper accentuation and aspiration of words in the Homeric or Attic dialects and in general usage, respectively. He also wrote important works on *Corruptions* (*sc.* of word forms), *Derivations*, *Orthography*, *Nominal Declension*, and a *Symposium*, which perhaps portrayed a learned conversation about etymologies, Attic words, and other questions.

Method

Apollonius and Herodian conceived of the Greek language as an ordered system: just as the alphabet had an order, so did the parts of speech, both in their listing (first noun, second verb, etc.) and in their roles in the construction of the sentence. At all levels, from letters to syntactic construction, the language was subject to corrupting processes or *pathê*, such as repetition, ellipse, syncopation, reduplication,

He also wrote important works on *Corruptions* (*sc.* of word forms), *Derivations*, *Orthography*, *Nominal Declension*, and a *Symposium*, which perhaps portrayed a learned conversation about etymologies, Attic words, and other questions.

Method

Apollonius and Herodian conceived of the Greek language as an ordered system: just as the alphabet had an order, so did the parts of speech, both in their listing (first noun, second verb, etc.) and in their roles in the construction of the sentence. At all levels, from letters to syntactic construction, the language was subject to corrupting processes or *pathê*, such as repetition, ellipse, syncopation, reduplication,

lengthening, shortening, and transposition. The basic method employed by Apollonius and Herodian, 'pathology', involved tracing these alterations: first, a rule was established by observation of the preponderance of cases or by analogy with similar formations; then deviations from the rule were explained by showing which corruptive processes occurred, and in which order, to produce the deviant form from the original 'correct' or 'full' form. This process was known as 'establishing' a form, or 'canonizing' it, bringing it into conformity with a rule, not by altering it to fit, but by showing how it derived from the rule-following form; if more than one form was found in the tradition or advocated by grammarians, the same process could indicate the preferable form. Establishing a form required application of a set of criteria or 'canons' of the discipline: analogy, dialect, etymology, and history or tradition. Of these, analogy, the comparison of relevantly similar words or constructions, was clearly the most important for Apollonius and Herodian and it lies behind Herodian's establishment of inflectional classes governed by rules or canons.

For Apollonius, syntax was the manipulation of intelligible items – such as gender or number – subsisting in dependence on word forms, so that their combination produced the 'congruence' or 'regularity' (*katallêlotês*) of a complete sentence. Only the intelligibles, not the words themselves, could be in harmony or conflict with one another, but only the words, not the intelligibles themselves, could be manipulated directly. Thus, 'Socrates walk' would be ungrammatical or 'incongruent' (*akatallêlon*) because placing these two word forms together also juxtaposes two conflicting intelligibles, the singularity and plurality, subsistent on the forms of their respective endings. Apollonius (*Syntax* 51.11) calls his *Syntax* an investigation of *katallêlotês* and in it he sets out the norms for producing such congruence in a sentence, while tackling questions that arose from particular, especially poetic, constructions by showing how they arose from the normal prose syntax.

Influence

Apollonius' works were mined by later grammarians and fragments appear frequently in the early Byzantine commentaries on Dionysius Thrax's *Art of Grammar* and the works of George Choeroboscus (early 9th century A.D.). His *Syntax* was the principal source of Priscian's (6th century A.D.) syntactical studies in the *Institutes*, as well as those of the Byzantine Maximus Planudes (ca. 1216–1310 A.D.).

Herodian's prosodic studies on Homeric words were excerpted in the late antique commentaries on the poems and became thus an important part of the Byzantine commentaries on Homer. The first 19 books of the *General Prosody* survive in two epitomized versions and their influence is present in all Byzantine work on accent and aspiration, and Herodian's *Orthography* had a similar influence on Byzantine spelling manuals. His works on nominal inflection formed the basis of later work systematizing the canons of inflection.

Applicational Grammar

In linguistics, as in all other areas of intellectual activity, ideas catch on not just because they are good but also because they arrive at the right time and in the right place. Developed at the wrong time and in the wrong place, Applicational Grammar (AG) is nonetheless a remarkable, if ultimately unsuccessful, achievement.

Background

Applicational Grammar (AG) was developed between the early 1960s and the mid-1970s by Sebastian Konstaninovich Shaumjan of the Institute of Russian Language at the Soviet Academy of Sciences. The first versions of the model were phonological; a detailed account of the model applied to syntax was published in Shaumjan (1965).

In 1965, Chomskyan transformational generative grammar was becoming the major formal model in North America and was beginning to spread to the UK and other countries. Montague's categorial grammar would not be published until 1970 (Montague, 1970a,b). Shaumjan's work from the early 1960s was not well received by North American generativists, and the translation of his 1965 book (Shaumjan, 1971) went unnoticed in the excitement over Montague Grammar. Nonetheless, Shaumjan's theory is no less rigorous than Montague's; he draws on a wider range of logical and linguistic theory, and his model is informed by knowledge of a number of languages in addition to English. His treatment of certain constructions is interesting; for example, Shaumjan (1965) proposes an analysis of complement clauses that anticipates Thomason (1976).

Shaumjan (1977) extends AG to handle semantic structures and the mapping of semantic structures onto syntactic structures. This later version of the grammar is influenced by generative semantics and the work of Fillmore on lexical decomposition, and also by Kilby (1977). Shaumjan (1977) was really innovative, however, in attempting to combine categorial grammar and what is now known as Situation Semantics.

The focus here is on Shaumjan (1965, 1971), because that model exhibits most clearly the properties distinguishing it from other generative models.

The Properties of Applicational Grammar

The Basic Units

The basic units are *term* and *sentence*, as is usual in categorial grammar. *Term* is represented by α, *sentence* by β. Other units, derived by combining the two basic ones, are interpreted thus: e.g., $\alpha\beta$ – a unit
